Arsenic
Test your well for arsenic at least once so you know how much arsenic is in your drinking water and you can make an informed decision about whether to take further action.

Arsenic occurs naturally in rocks and soil across Minnesota and can dissolve into groundwater. Drinking water that contains arsenic can increase your risk of cancer and other serious health effects. Unfortunately, there is no way to know the arsenic level in water before a well is drilled. Arsenic levels can vary between wells, even within a small area. You cannot taste, see, or smell arsenic in your water.

Drinking Water Standard
The maximum level of arsenic the U.S. Environmental Protection Agency (EPA) allows in community water systems is 10 micrograms per liter (µg/L*). However, consuming water with arsenic at levels lower than the EPA standard over many years can still increase your risk of cancer. As a result, the EPA has set a goal of 0 µg/L of arsenic in drinking water.

*1 µg/L is the same as 1 part per billion (ppb).

Health Risks
Consuming water with even low levels of arsenic over a long time is associated with diabetes and increased risk of cancers of the bladder, lungs, liver, and other organs. Ingesting arsenic can also contribute to cardiovascular and respiratory disease; reduced intelligence in children; and skin problems such as lesions, discoloration, and the development of corns. Health impacts of arsenic may take many years to develop.

Test Your Well Water
Test for arsenic at least once
MDH recommends you use an accredited laboratory to test your water. Contact an accredited laboratory to get sample containers and instructions, or ask your county environmental or public health services if they provide well testing services.

New wells are tested for arsenic
As of August 2008, well contractors test each newly drilled well for arsenic and share the results with the well owner and the Minnesota Department of Health (MDH).

Find existing test results: Use the online Minnesota Well Index or contact MDH for test results for a well constructed since 2008.

Consider confirming the arsenic level
If arsenic was NOT detected in the first sample, your water is unlikely to have arsenic later.

If arsenic was detected in your new well, you may want to retest your well about six months after construction. MDH research found that when arsenic is detected in a new well, the level may increase or decrease in the first few months after construction.

MDH highly recommends you take action if arsenic levels are above 10 µg/L.

Water treatment units that reduce arsenic:
- Reverse osmosis
- Distillation
- Oxidation filtration
- Adsorptive media
- Anion exchange

Learn more about treatment options in the “Water Treatment Units” document. A water treatment specialist can help you select the best option for you and your household.

Water with arsenic is safe to use for other things (unless the level is above 500 µg/L). Since your skin does not easily absorb arsenic, your water is safe for washing dishes and clothes, brushing teeth, showering, bathing, and watering plants (including vegetables).

Tips for reducing other contact with arsenic
- Do not burn wood treated with arsenic.
- Be aware of ingredients in medications and folk remedies.
- Seal arsenic-treated wood structures.
- Make sure children wash their hands.
- Wash and peel vegetables grown underground (e.g., potatoes, carrots).
- Eat less rice, cereal grains, or other foods that contain arsenic.
- Do not use old pesticides and soil supplements if they contain arsenic.

Protect Your Family
If arsenic is detected at any level, consider:
- Installing a treatment unit or
- Using a different drinking water source.

Drinking water with even low levels of arsenic over many years increases the risk of diseases such as cancer.

Protect your health!
Test your well water for:
- Coliform Bacteria (Every year)
- Nitrate (Every other year)
- Arsenic (At least once)
- Lead (At least once)
- Manganese (Before a baby drinks the water)

Testing is even more important if young children drink the water.

MDH may recommend you test for additional contaminants based on where you live.
Arsenic in Minnesota Water

Arsenic has been detected in about 40 percent of new wells drilled since 2008 in Minnesota.\(^1\) About 10 percent of Minnesota’s private wells have arsenic levels higher than 10 µg/L.

Arsenic is in groundwater throughout the state, but it is more likely in some areas. The map on the front shows where arsenic is found most often in Minnesota wells.\(^2\) The way glaciers moved across Minnesota affects where arsenic is found in sediment and groundwater. Arsenic levels can vary between wells, even within a small area. Some wells have arsenic levels as high as 350 µg/L; however, most results are below 50 µg/L.

Background Information

For most people, food and water are the biggest sources of arsenic exposure. There are two forms of arsenic:

- **Inorganic arsenic** is the type found in drinking water and is the more harmful type of arsenic. It is also found in rice, cereal grains, and other foods. It forms when arsenic combines with metals and elements other than carbon.

- **Organic arsenic** is the most common type of arsenic found in food. It is common in fish and shellfish and is less harmful to health than inorganic arsenic. It is formed when arsenic combines with carbon.

While most arsenic in Minnesota’s environment occurs naturally, some comes from human activity. Arsenic was an ingredient in some pesticides and was used as a wood preservative in the past.

---

\(^1\) The detection level for arsenic is usually 2 µg/L.
