For the electronic version of this document and for Part Two (disease and injury data), visit the Minnesota Department of Health website: www.health.state.mn.us/statewidehealthassessment. The Health of Minnesota: Statewide Health Assessment was produced in collaboration by the Minnesota Department of Health and the Healthy Minnesota Partnership. Partial funding for this project was provided by the following: PHHS Preventive Block Grant No. 2B01DP009029-10; the Office of Disease Prevention and Health Promotion, U.S. Department of Health and Human Services, through John Snow, Inc. (JSI), July 2011-June 2012; and Cooperative Agreement Number CD10-1011 from the Centers for Disease Control and Prevention. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of any of the above funding organizations. Upon request, this material will be made available in an alternative format such as large print, Braille or cassette tape.
Minnesota is a great place to live, and Minnesotans are on average among the healthiest people in the nation. Businesses and industries thrive here, too, and the lakes, fields, forests and rivers in the state provide a beautiful backdrop for everyday activities. Many individuals and organizations throughout the state share the mission of protecting, maintaining and improving these conditions and the health of Minnesotans.

This document presents an assessment of health in Minnesota, in the broadest sense of that concept. Health is defined by the World Health Organization as “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity.” This kind of health is not just about individuals, but includes families, communities and systems, and is a result of the interaction of complex networks of conditions and factors. This kind of health starts long before illness is manifest: it begins in homes and schools, in jobs and workplaces, and in communities. Ultimately, it reflects the 1988 Institute of Medicine mission of public health, “fulfill[ing] society's interest in assuring the conditions in which people can be healthy [emphasis added].”

To reflect this understanding of health, The Health of Minnesota discusses a wide array of indicators and information about the conditions and factors affecting health, as well as indicators of health status. The assessment is presented in two parts: Part One provides information about physical, social, and behavioral factors for health in Minnesota; Part Two presents data on health outcomes related to disease and injury.

The Healthy Minnesota Partnership

Minnesota’s statewide health assessment was prepared under the auspices of the Healthy Minnesota Partnership, a multi-sector group of community leaders. The Partnership is charged with developing innovative public health priorities, goals, objectives and strategies to improve the health of all Minnesotans, and to ensure ownership of these priorities and strategies in communities across the state. The Health of Minnesota is the first step toward fulfilling this charge, and provides the basis for creating a Healthy Minnesota 2020 statewide health plan. The Partnership hopes that assessing and addressing a broad array of health-related conditions and factors will change the conversation around health, energize the public, private and nonprofit sectors, and create a groundswell of community efforts to improve health in every Minnesota community.

Public Input

A draft of The Health of Minnesota was made available for review and feedback online during January and February 2012. The Healthy Minnesota Partnership was instrumental in encouraging their constituencies to review the document. Over 100 responses were collected through the online survey, making thoughtful and helpful suggestions for improving the document. In addition, the Healthy Minnesota Partnership received several letters from

* Partners range from state agencies to communities of color, local public health, elected officials, nonprofits, health care providers and the community. Please visit the Appendix for a list of Healthy Minnesota Partnership members.
constituent groups offering additional analysis and identifying issues of their particular concern. The comments and suggestions received were incorporated into *The Health of Minnesota* wherever possible.

**Limitations**

While this statewide health assessment presents many important issues and topics, it does not present every possible health-related issue. The issues and indicators chosen are intended to reveal the scope and complexity of population health, but space does not allow for each of them to be thoroughly documented. Therefore, the assessment should not be considered a formal study or research document investigating the causes of each issue raised or providing a detailed analysis of the data. Volumes have been written on many of these issues, and references are provided throughout to enable access to additional information.

In some cases, information that could greatly inform a statewide health assessment is simply not available. This may be because data are not available at the state level, or data are not stratified by race/ethnicity, income, sexual orientation, etc. When race/ethnicity data are gathered, analysis may be further limited due to a lack of data stratification by more specific racial categories, such as U.S.-born vs. African-born for the African-American population, or the many ethnicities and cultures represented in the category of Asian-Pacific Islander. In other cases, especially when it comes to understanding the interactions of the many factors that contribute to health, data are lacking in part because the theoretical models are still being developed.

The assessment also does not include the many programs, services, and strategies that are currently (or could be) implemented to address these health-related issues, either by the Healthy Minnesota Partnership, by the Minnesota Department of Health, or by other stakeholders. The statewide health assessment is not, in other words, Minnesota’s statewide health plan; that document called *Healthy Minnesota 2020* will follow later in 2012.

**A Framework for Assessing Health**

Health is a product of many conditions and factors. Nationally and internationally, a growing body of research is showing how living conditions and social and economic opportunity determine health outcomes. It can be difficult to visualize the broad factors that influence health. Dahlgren and Whitehead propose the model at right, in which the individual with unique biological characteristics is surrounded by community, place, and system-based conditions and factors. A similar model, called the ecological or social ecology model, is used in a variety of academic and practice fields in order to better understand the larger forces that impact individuals.

The movement from an understanding of health focusing on the individual to one focused on communities and systems health also is evident in the development of *Healthy People*, the national agenda for health developed by the U.S. Department of Health and Human Services.
**Healthy People 2020 Overarching Goals**

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death
- Achieve health equity, eliminate disparities, and improve the health of all groups
- Create social and physical environments that promote good health for all
- Promote quality of life, healthy development, and healthy behaviors across all life stages

The U.S. Department of Health and Human Services describes similar factors that influence the development of a healthy community:

“A healthy community is one that continuously creates and improves both its physical and social environments, helping people to support one another in aspects of daily life and to develop to their fullest potential. Healthy places are those designed and built to improve the quality of life for all people who live, work, worship, learn, and play within their borders—where every person is free to make choices amid a variety of healthy, available, accessible, and affordable options.”

Clearly, a number of complex and subtle interrelationships among many conditions and factors affect health. For example, an individual’s level of education is associated with the likelihood that s/he smokes, and a higher risk of cancer is correlated with smoking. However, it is also important to acknowledge the role other factors play on a person’s likelihood of becoming and staying a smoker: level of education influences his/her occupation, which influences his/her overall stress level, which influences his/her interpersonal relationships, which influences his/her likelihood of smoking. Many factors circle around themselves in this way, influencing an individual’s health in cyclical manners.

Childhood experiences seem to particularly influence a person’s health in the immediate and distant future. Beneficial and harmful events in those early years, especially positive or negative interactions with adults, affect the biology of the body, and a person’s entire life.

**How early experiences get into the body: A biodevelopmental framework**

*Source: Harvard University, Center on the Developing Child. (2010).*
Greater opportunities for health, beginning in childhood and continuing throughout life, lead to healthier living, which leads to better lifetime health.

It is both important and challenging to incorporate community, environment, and system factors into a statewide health assessment. Without recognizing the relationship among many factors, organizations cannot develop effective strategies to improve health, but integrating all relevant factors into a strategy can be challenging, time-consuming, and difficult to measure.

**Organization**

*The Health of Minnesota* highlights a variety of factors and conditions. The structure of the document developed from conversations within the Healthy Minnesota Partnership, in which the Partnership agreed that Minnesotans require the following to be healthy:

- A healthy start in life
- Supportive families, friends and communities
- Safe and welcoming places to live, learn, work, play, and worship
- Knowledge, with the freedom, capacity, and desire to act on that knowledge
- Fair employment and a living wage
- Access to systems designed to meet their needs (health care, public health, social safety net, transportation, and more)

**Part One** of this statewide health assessment reflects this broad way of thinking about health, and is organized around three major themes that reflect *conditions* and *factors* that assure health:

- **Minnesota: People and Place**: Who we are and our natural environment; the people of the state; and the air, water and land that surround them
- **The Opportunity for Health in Minnesota**: The social, economic, and community factors that have a potent influence on our health
- **Healthy Living in Minnesota**: The ways in which individuals and communities act to protect and improve health

**Part Two** of this assessment focuses on *outcomes* of health, including the diseases, conditions, and injuries that health-related strategies, programs, and services hope to prevent.

**General Health Status**

Minnesota is considered to be one of the healthiest states in the nation. The United Health Foundation has ranked states’ overall health status since 1990, and for the first 18 years Minnesota consistently landed in the top five. In the last three years, however, Minnesota’s rank has slipped to sixth, and remains there.

According to the 2011 *America’s Health Rankings* report, Minnesota’s strengths include:

- Low rate of death related to cardiovascular disease (Rank: 1)
- Low rate of uninsurance (Rank: 3)
- High rate of high school graduation (Rank: 3)
Challenges identified by the report include:

- Low rate of public health funding per capita (Rank: 46)
- High prevalence of binge drinking (Rank: 44)

Minnesota’s overall health ranking in the United States: 1990-2011

![Graph showing Minnesota's overall health ranking from 1990 to 2011]

The report also found that Minnesota ranks lower on determinants of health (that is, factors that influence a person’s health) than on health outcomes (i.e., disease and injury), raising concern that the overall health of the state’s population may decline over time as outcomes catch up with determinants.

Health Disparities and Health Equity

Reports like *America's Health Rankings*, which rely on overall averages, can obscure an important issue: health disparities. When it comes to the differences in health status between populations, Minnesota is far from equal. In reality, populations of color and American Indians in Minnesota experience higher rates of many chronic and infectious diseases and premature death.

As noted above, health is not just the absence of disease, but a state of “well-being” in every aspect of life. That means that health starts in homes and schools, jobs and workplaces, and places of worship, socialization, and play. With this understanding of health, the sources of health disparities become more evident. Many Minnesotans, especially populations of color and American Indians, experience inequitable living conditions and unequal treatment in many aspects of life. Historical, institutional and personal racism have contributed greatly to these inequities, which in turn lead to poorer health status. Throughout this assessment, the data reveal that disparities in health status and health determinants are widespread and persist throughout a person’s lifetime: from their education to their employment opportunities and subsequent income; from infant mortality to cancer rates to health care access; and from early childhood through adulthood.

These persistent inequalities in our state (in environment, opportunity, and healthy living) are demonstrated throughout this assessment, and are illustrated most starkly in a comparison of mortality rates by race and ethnicity. As illustrated in the chart and accompanying table below, the rate of death in the American Indian population, Minnesota’s most historically established...
population, is much higher than in the state’s white population across all age groups except the elderly, and death rates in the African-American population are consistently nearly twice as high as the state’s white population, aside from the elderly.\textsuperscript{12}

**Disparities* in mortality in Minnesota: 2006-2010**

American Indian and African-American Minnesotans experience substantially higher mortality rates at earlier ages.

*Disparity ratios are calculated by dividing the rate for a given population (African-American, American Indian, Asian or Hispanic) by another rate (white) for a selected health indicator to determine how much more likely a particular event is to occur in one population compared to another.

Source: Minnesota Department of Health, Minnesota Center for Health Statistics. (2011).\textsuperscript{13}
Minnesotans represent every populated continent on the globe, and our faces reflect that diversity. Minnesota’s geography is also diverse, and includes prairies, bluffs, forests, lakes, and rivers, including the mighty Mississippi. In northwestern Minnesota, residents say that one can “see the weather coming” across the rolling prairie, while southeastern Minnesota is sculpted in dramatic relief along the Mississippi and St. Croix river bluffs, and glacier-carved lakes and thick coniferous forests are scattered across the north of the state.

Minnesotans share an appreciation for the beauty of their state and the resourcefulness of their communities. This section, *Minnesota: People and Place*, discusses urban and rural population trends; immigration and the increasing diversity of the state’s population; the state’s changing age profile; Minnesota’s water, weather and air; and the roads, bridges and walkways that connect Minnesotans to each other.

**Urban and Rural Population Trends**

*Minnesota counties and tribal nations: 2012*
Geographically, Minnesota is largely a rural state. More than half of the state’s population, however, resides in the Twin Cities metropolitan area in the east-central region of the state.

- Minnesota had 5.3 million total residents in 2010
- Minnesota is divided into 87 counties and contains 11 federally recognized American Indian tribes: seven Anishinaabe (Chippewa, Ojibwe) reservations and four Dakota (Sioux) communities
- Seven of the 10 largest cities are in the seven-county Twin Cities metropolitan area as of 2010: Minneapolis, 382,578; St. Paul, 285,068; Bloomington, 82,893; Brooklyn Park, 75,781; Plymouth, 70,576; Eagan, 64,206; Woodbury, 61,961. The other three largest cities are in the southeast (Rochester, 106,769); northeast (Duluth, 86,265); and central Minnesota (St. Cloud, 65,842)

**Population change in Minnesota by county: 2000-2010**

Much about Minnesota is changing. Once very demographically homogenous, Minnesota’s racial and ethnic diversity is increasing rapidly in some areas. People throughout Minnesota are developing a new and expanded sense of what it means to be Minnesotan. As the state’s population ages, communities will be confronted with challenges and opportunities in meeting the unique needs of older Minnesotans.

---

**Populations in Minnesota’s suburban counties have grown over the past decade, while the state’s southwest and northern counties have lost the greatest number of residents.**
Minnesota’s population grew by 7.8 percent between 2000 and 2010 (at about the same rate as South Dakota, but faster than North Dakota, Wisconsin, or Iowa). Rural areas of the state, however, continue to lose population, while the population in areas surrounding the Twin Cities metropolitan area continue to grow rapidly.

**Immigration and Growing Diversity**

While Minnesota is still far from the most diverse state in the U.S., this is gradually changing. In 1990, populations of color and American Indians in Minnesota represented just over 6 percent of the total population. In 2010 that had grown to 15 percent. The Hispanic population grew by 364 percent during that time, and the African-American population grew by 189 percent. In 2025 the state’s population of color is expected to be around 22 percent, and in 2035, if this trend continues, it will reach about 25 percent.\(^{14}\)

*Source: U.S. Census Bureau. (2011).*\(^{16}\)
The state’s diversity is increasing primarily through immigration. Minnesota attracts a wide range of immigrants to the state from other parts of the U.S. and from other countries, who move here to attend school, start businesses, work in Minnesota industries, and join family members.

Minnesota’s diversity is quite varied when considering places of origin. Minnesotans include new residents from Mexico, Laos, Somalia, Vietnam, Canada, Ethiopia, Korea, Liberia, Germany, Burma, and Bhutan, to name just a few. This diversity within racial and ethnic categories (especially from Asia and Africa) presents nearly as many challenges as diversity within the whole population: for example, at least 19 different countries are represented among Asian immigrants to Minnesota. The peoples from these areas bring a wide range of backgrounds, experiences, cultural practices, languages, and unique health concerns to Minnesota.  

It is also important to remember that Minnesota’s growing racial and ethnic diversity is not limited to the Twin Cities metropolitan area. The southwestern region of Minnesota, in particular, has experienced a dramatic increase in immigrant populations.

Change in the distribution of people of color in Minnesota: 1990-2010

Immigrant groups, on average, tend to be younger than the state’s white population, in part because of the age of the immigrants themselves, and also because they often have more children. This is also true of Minnesota’s populations of color: more than one-third of each population of
color and American Indians in Minnesota are younger than 18, while only one-fourth of the state’s white population is comprised of children.

**Population age distribution in Minnesota: 2010**

![Population age distribution chart](chart.png)

**Aging and Retirement**

Both Minnesota and the U.S. have aging populations. From 2000 to 2010, the proportion of Minnesotans under the age of 45 decreased by 2 percent while the proportion of persons 45 and over increased by 27 percent; the proportion of the state’s population over 65 will increase as the baby boomer generation continues to move toward retirement age. The largest increases in Minnesota’s population from 2000 to 2010 were to age groups 50 years and older.

</table>

This is especially true in rural areas of Minnesota, in which the aging population is expected to grow more substantially than that in the Twin Cities metropolitan area. The proportion of older residents is expected to be largest in Minnesota’s rural western and northern counties.

**Projected population age 65 and over in Minnesota: 2035**
Water, Weather, and the Air

Minnesota is a beautiful and geographically diverse state.

- The total land area of Minnesota is 79,610 square miles (or nearly 51 million square acres)
- Minnesota has 58 state forests (totaling almost 4 million square acres), 72 state parks, and thousands of lakes (see below)
- The state’s seasons include mild, wet springs; dry autumns; humid summers; and cold, snowy winters—with a great deal of variation within each of these seasons

Water

In the language of the state’s indigenous Dakota, minne means water, and Minnesota means water that reflects the sky. Minnesota is rich in water resources, with nearly 12,000 lakes over 10 acres, more than 6,500 natural rivers and streams traveling 69,000 miles, and 9.3 million acres of natural wetlands. Six percent of the state is covered with this water that reflects the sky—more than any other state.

The health of the water and that of the people of Minnesota are closely linked. Monitoring water quality for health involves protection of the natural environment as a source of drinking water, and regulation of the built environment that delivers water to Minnesota residents and creates potential sources of contamination.

Area covered by water in Minnesota

| Total area covered by lakes and rivers (deep water) | 2,560,299 acres |
| Total surface water area, including wetlands | 13,136,357 acres |

Source: Minnesota Department of Natural Resources. (2008).

Drinking water comes from either a surface source (i.e., water found above ground in rivers, lakes, and streams) or a groundwater source (i.e., water found in underground aquifers, in the pores between sand, clay, and rock formations). Approximately 70 percent of all Minnesotans rely on groundwater as their primary source of drinking water, and 1 million Minnesotans rely on private wells. While most of the state has access to abundant groundwater, the geology of southwestern and northeastern Minnesota limits the amount of groundwater available for domestic use and economic development. In some parts of the Twin Cities metropolitan area, increasing consumer and commercial demand reduces groundwater stores enough to pose a serious challenge for the future.

Drinking water can be contaminated by man-made chemicals or by natural sources like heavy metals in rock and soil. While existing in nature, water contains impurities and most are harmless; however, at certain levels, some bacteria, minerals, and man-made chemicals can make drinking water harmful to health. Primary groundwater quality concerns in Minnesota include naturally occurring arsenic and radium, and human-influenced pesticides, fuel oils, industrial chemicals, and sources of nitrate (e.g., fertilizers, animal wastes, human sewage).

Based on existing monitoring data, it is now estimated that about 10 percent of all private wells in Minnesota have arsenic levels of 10 µg/L or more.
In addition to these known contaminants, Minnesota’s water supplies may also contain contaminants of emerging concern¹ like endocrine disrupting chemicals, prescription and non-prescription pharmaceuticals intended for humans and livestock, additives to personal care and consumer products, and some current-use pesticides. State government agencies become concerned if appropriate human health-based drinking water guidance for these substances is unavailable, or when new information about these substances suggests that the health risks from exposures should be reexamined.

**Weather and Climate**

Minnesota typically has cold, snowy winters and hot, humid summers. Temperature extremes can create health challenges, especially for elderly residents and for those with special health concerns. Minnesota’s normal temperatures range from an average low of 6°F in the winter, to an average high of 70°F in the summer (with an average of 83°F in July). Minnesota also receives anywhere from 18 to 36 inches of liquid precipitation (in rain and snow) each year. These

---

¹ “Emerging concern” indicates to health officials the importance of staying abreast of new or changing health or exposure information on these contaminants.
averages, however, mask the range of extremes experienced by Minnesota from year to year, including blizzards and heat waves.\textsuperscript{33}

Climate change and the ensuing effects on weather patterns may also affect health in Minnesota. Weather data for Minnesota show a trend toward increasing warmth, especially in recent decades, and Minnesota has seen more frequent heavy downpours, record-breaking spring floods, and a decrease in the thickness of lake ice in recent years.\textsuperscript{24} Four of the five warmest years on record have occurred in the last 10 years. Five heat episodes in the summer of 2011 resulted in National Weather Service warnings or advisories for Minnesota counties. \textsuperscript{25} Unusually warm summers reduce air quality, exacerbate pollution, increase insect populations (as well as rates of tick-borne disease\textsuperscript{\textdagger}), and affect water quality. Extreme heat events are particularly concerning for vulnerable populations, including those 65 and older, children under five, people living in poverty, and individuals with pre-existing conditions like allergies or asthma.

Consistently higher summer temperatures also foster increased insect populations and the increased potential for the spread of disease by insects, while flooding increases breeding grounds for disease-carrying insects and increases the potential for waterborne infections.

**Air Quality**

**Radon**

Radon is the most critical air quality issue in Minnesota, especially in homes and living spaces. It is a colorless, odorless gas that occurs naturally in the environment, and is the leading cause of lung cancer among non-smokers. There is no safe level of radon for humans. The risk for lung cancer increases with more concentrated levels of radon gas and increased exposure.

Radon seeps from the earth and enters homes in a variety of ways, such as through cracks in floors and walls, construction joints, or gaps around service pipes. In Minnesota, one of every three homes has radon levels at levels that pose a significant health threat (over 4 pCi/L). All Minnesota counties are designated as either High or Moderate Radon Zones.\textsuperscript{27}

\textsuperscript{\textdagger} For more information on rates of tick-borne disease, please refer to Supplement: Disease and Injury.
Air Pollution

Air pollutants can affect health, the environment, and individuals’ quality of life. Fossil fuel-based power plants, motor vehicles, lawn and garden equipment, paints and solvents, and fires are all common sources of air pollution. Elevated levels of air pollutants may cause respiratory diseases or cancer, and can affect health in other ways.

Outdoor pollutants contribute to odors and smog, diminish the protective ozone layer, and contribute to other environmental problems like acid rain and global climate change. Indoor pollutants like mold, radon, tobacco smoke, carbon monoxide, and chemical emissions from products and furnishings are some of the important pollutants that may be present in homes, schools, buildings, and other indoor environments.

Residents throughout the state experience a large number of unhealthy air quality days, although the Twin Cities metropolitan area experiences the greatest number of unhealthy days. The high number of unhealthy air quality days in 2010 in the Twin Cities was likely the result of an unusually calm and stagnant winter (which can allow pollution levels to build to potentially unhealthy levels), and likely not the result of changes in air pollution emissions.
Unhealthy air quality days in Minnesota: 2006-2010 average and 2010

Unhealthy air quality days occur when the Air Quality Index (AQI) reaches a level that is harmful for sensitive groups, including people with respiratory or cardiovascular disease, children, the elderly, and people participating in activities that require heavy or extended exertion. Source: Minnesota Pollution Control Agency. (2012).

Residents throughout the state experience a large number of unhealthy air quality days, although the Twin Cities metropolitan area experiences the greatest number of unhealthy days.

Roads, Highways, and Bridges

Minnesota’s network of roads, highways, railways, and bridges forms an integral part of the landscape, and the transportation infrastructure has a significant influence on the state’s environment for health. Nearly every Minnesotan comes into daily contact with roads, highways and bridges in order to reach the places he or she lives, works, and learns. Experiences on these roadways can affect mental health (e.g., scenic drives, smooth travel, the stress of heavy traffic, aggressive or unsafe drivers) as well as physical health (e.g., physical activity, air pollution, noise, unsafe driving conditions, injury).

State bridges in Minnesota in poor condition, historical and projected(*): 2006-2015

Poor pavement ride quality in Minnesota, historical and projected(*): 2006-2015

The integrity of Minnesota’s transportation infrastructure is important, therefore, for health. In 2011, just over 3 percent of bridges on state principal arterial roads were in poor condition. By 2015, only 2 percent of bridges are expected to be in poor condition. Nationally, Minnesota has the fourth lowest percentage of bridges classified as structurally deficient or functionally obsolete; less than half the national average.\textsuperscript{31}

State pavement condition has been declining due to age and competing investment needs. After significant improvement in 2010, only about 7 percent of state trunk highway miles in Minnesota were in poor condition. However, even with significant planned investments, poor pavement conditions are expected to increase to over 8 percent of state trunk highway miles by 2015.\textsuperscript{32}

Traffic congestion also plays a major role in the daily lives of many people in the state, especially in the Twin Cities metropolitan area. More than 50 percent of roadway travel in the state occurs on the 13 percent of roadway miles in the Twin Cities. The region’s congestion delay compared to other major metropolitan areas also can affect economic competitiveness. Effective management of traffic congestion improves the economy, quality of life, safety, and air quality.

Twin Cities freeway congestion decreased slightly in 2011 (to 21 percent), but this is still among the highest levels of the last decade.

\textbf{Congested urban freeway miles in the Twin Cities, Minnesota: 2002-2011}

\end{figure}

\textit{Source: Minnesota Department of Transportation. (2012).}\textsuperscript{33}

For more information on the role of transportation in health status, please refer to the section of this assessment titled “The Opportunity for Health in Minnesota.”
Opportunities for health among Minnesota residents begin within their families, neighborhoods, workplaces, and schools, where Minnesotans live, love, worship, play, work, and learn. A growing body of research shows that entire communities benefit when that community’s members invest together in the opportunity to be healthy.

Minnesotans often do not share the same opportunities for health, however, depending on their race, ethnicity, income, and geography, among other factors. For example, Minnesotans of color and American Indians have more limited access to the kinds of opportunities for health discussed in this section: a high school education, employment, housing and home ownership, healthy outdoor and indoor environments, social connectedness, community and personal safety, and access to health care and public health.

Education and Employment

Education

Health and learning are closely connected. Education is an important predictor of health because it both shapes and reflects multiple factors that affect people’s life chances. Investing in education can be “the single most effective intervention we can make to improve health outcomes and tackle inequities.”

Health affects learning at all ages, from early childhood through adolescence, to adulthood. Early reading and literacy stimulate brain development in young learners, help develop their analytical and communication skills, and influence their intellect and behavioral patterns. These in turn shape future opportunities and achievement.

Certain health behaviors, too, are strongly associated with education. For example, 33 percent of Minnesotans who do not have a high school degree smoke, compared with 25 percent of high school graduates, 21 percent of those with some post-secondary education, and 9 percent of college graduates.

Minnesota high school students graduating on time: 2010

![Bar chart showing graduation rates by race/ethnicity]

Source: MN Compass, Minnesota Department of Education. (2011).

Minnesota’s white and Asian students graduate from high school at a higher rate than students of other races/ethnicities.
High school graduation rates are a consistent marker of education opportunity among Minnesota’s various populations. In 2010, the four-year rate of high school graduation was highest for white and Asian populations and lowest for American Indian and African-American populations.

**Employment**

Education is one gateway to employment. Stable and secure employment influences health not only by being a source of income, but by providing access to health insurance.

**Average annual unemployment in Minnesota: 2010**

[Map showing unemployment rates across Minnesota]

**Unemployment and Racial Disparities**

Significant disparities in employment persist in Minnesota, especially in the Twin Cities area. A recent analysis of unemployment in the nation’s largest metropolitan areas shows that the Minneapolis-St. Paul-Bloomington census division currently experiences the worst relative unemployment disparity between African-Americans and Caucasians in the United States. This same census area has the second-highest rate of African-American unemployment in the country: 20.4 percent. 37

Income and Poverty

Income

Employment is important, yet income involves more than money earned from a job. It also includes assets (like a bank account or equity in an owned home) and access to a variety of economic resources. Income influences the opportunity people have to choose where to live, to purchase nutritious food, to participate in a wide variety of physical activities, especially those that require fees or special equipment, and to have leisure time. Jobs and job-related income, however, remains a steady marker of one aspect of a household’s wealth. In Minnesota, African-American and American Indian populations have household incomes that are almost half that of Asian and white populations.
Poverty

Poverty, often resulting from limited income or a lack of income, is linked to health in many ways. Poverty limits choices: in education, in employment, and in living conditions, among others. Poverty limits access to safe places to live, work, and play, and places to buy healthy food. Poverty can foster obesity by forcing people and families to rely on cheap sources of food, which tend to be plentiful but high in calories and low in nutritional value.

Poverty also is deepened by a lack of assets. Nearly two-thirds of African-American Minneapolis-St. Paul residents, compared with about one-fourth of the cities’ white residents, live in ‘asset poverty,’ meaning they do not have enough assets to live above the poverty level for three months if they lose their main source of income.

Children in Poverty

Poverty rate among Minnesota children under age 18: 2010

Minnesota children of color live in greater poverty than white children.

A growing body of research is demonstrating that children who are raised in families experiencing chronic stress created by long-term poverty (<100% of the Federal Poverty Level) are at much greater risk of significant and long-term deficits in health. Poverty among Minnesota’s children is not evenly distributed. A far-greater percentage of children of color live in poverty than white children. And children who grow up in poverty are very likely to remain in poverty as adults.

**Food Security**

Food security means having enough to eat, and being able to make healthy food choices. Adequate nutrition is particularly important for children, as it affects their cognitive and behavioral development. Children from food insecure, low-income households are more likely to experience irritability, fatigue, and difficulty concentrating on tasks, especially in school, when compared to other children.

**Food security* in Minnesota: 1996-2010 (three-year averages)**

<td>4.0%</td>
</tr>
</tbody>
</table>

* Denotes households experiencing food insecurity and very low food security.  

In 2010, more than 10 percent of Minnesota households struggled to afford enough to eat. Of these, just over 4 percent were categorized as “very low food security,” meaning they sometimes skimped on meals, or completely skipped them, for lack of money. Because of the economic challenges of single parenting, single women with children are nearly twice as likely to experience food insecurity as married couples with children.

Food insecurity is greater in rural Minnesota than in the metro area; some rural Minnesota counties have food insecurity rates of 12 to 14 percent.

**Housing and Home Ownership**

As part of the built environment, housing is a key factor for health. Older housing in particular can present multiple threats to health, including lead-based paint, lead solder in plumbing and in the soil, mold, and asbestos. Minnesota’s low-income families can often be found in older homes, as older homes are frequently more affordable.
Home ownership gives the occupants more control over their living environment, and can be a source of financial stability as an asset (home equity) that can be called on in a time of need. Home ownership also confers benefits on the community. Homeowners participate more in the civic and social life of their communities, help prevent and report crime, are more environmentally aware, and are more empowered to address environmental concerns in their homes and neighborhoods. Children benefit from residential stability when living in a permanent home, perform better in school, and have better health outcomes.47

The rate of home ownership among the Twin Cities metropolitan area’s white population is more than double the rate of that in the area’s African-American and American Indian populations.

The rate of home ownership in St. Paul and Minneapolis, Minnesota: 2006-2008

![Chart showing home ownership rates by race and ethnicity]

Source: Corporation for Enterprise Development (CFED). (2011).48

Rates of home ownership vary widely by race and ethnicity in Minnesota. A recent analysis of Minneapolis and St. Paul revealed that more than 60 percent of the white population in the Twin Cities metropolitan area owns a home, but barely a quarter of the African-American and American Indian populations in Minneapolis and St. Paul are homeowners.49

Outdoor and Indoor Environments

Natural and man-made (or built) environments contribute to health in a variety of ways. For example, everyone needs clean water to drink and air that is safe to breathe, but people also need schools, workplaces, and homes that do not expose them to physical or chemical hazards, and places to walk and play outdoors that are clean and free of debris.

In some communities, the built environment can be overtly hazardous, such as living near a toxic waste dump. Because income affects housing choice and more polluted areas are less desirable, families with lower income may have no choice but to live in housing with indoor hazards like foundation cracks allowing radon seepage, lead paint, and asbestos in the building materials. Outdoor hazards affecting health can include dilapidated sidewalks or no sidewalks at all, which is often the case in rural areas, making it difficult and dangerous for residents to walk or children to ride bikes. Many areas do not have ready access to public transportation; air pollution can pose a hazard high near major roadways and thoroughfares; and a lack of parks and playgrounds will prevent children from playing safely and instead encourage sedentary activities indoors.
Transportation

According to Healthy People 2020,

“A healthy community is one in which people have access to healthy foods, feel safe, have opportunities for physical activity, breathe clean air, have access to gainful employment and feel connected to opportunity. Transportation is access, thus, transportation is opportunity.”

Transportation links people and places, making it possible to get to work, for example, or to get from home to the grocery store. Transportation includes more than the state’s roads, walkways, or bridges: it encompasses the state’s public transit systems; policies that dictate the location and construction of roads; and guidelines for accommodating different kinds of users, for increasing physical activity, and for limiting the potential for driver, bicyclist, and pedestrian injury.

Environmental factors influencing physical activity in Minnesota and the United States: 2010

<table>
<thead>
<tr>
<th>Environmental factor</th>
<th>Minnesota</th>
<th>United States</th>
</tr>
</thead>

<td>17.7 percent</td>
<td>20.3 percent</td>
</tr>
<tr>
<td>Percent of census blocks with fitness center within one half-mile of block boundary</td>
<td>16.1 percent</td>
<td>16.6 percent</td>
</tr>
</tbody>
</table>

Walking provides a ready and inexpensive source of physical activity, thus community walkability is an important aspect of transportation. In a “walkable” community, residents are able to walk safely to school, neighbors, and shops. Walkable neighborhoods increase community-based activity and social connectedness. While in urban areas, crime, poor street lighting, and deteriorated sidewalks may pose barriers to walking, in suburban and rural communities distances are generally too great to walk, and there may be no sidewalks or other safe places to walk away from fast-moving traffic.

Parks and Playgrounds

Living near a park or playground is associated with higher levels of park use and physical activity among a variety of populations, especially youth. Similarly, having more parks and more park area (e.g., acreage) within a community is also associated with higher physical activity levels.

Lower-income populations and some racial and ethnic populations often have limited access to parks and recreational facilities in their neighborhoods, resulting in lower physical activity levels. If parks unpleasant or if they feel unsafe, neighborhood residents are less likely to use them.

Lead, Mold, and Asbestos

Some of the most common hazardous substances in outdoor or indoor environments are lead, asbestos, and mold, as well as less common elements in radiation and carbon monoxide.

One in five Minnesotans lives within walking distance of a park.
Minnesotans are exposed to lead in homes and in certain occupations (e.g., home remodelers, painters, workers in smelters or battery plants). Lead poisoning can cause learning, behavior and health problems in young children, and high blood pressure and kidney damage in adults.

Lead-based paint for household use was phased out of use beginning in the 1950s, and fully banned by 1978. Younger children (those less than six years of age) who spend time in homes with chipping or peeling paint built before 1978 are at the greatest risk of lead poisoning, for several reasons: their bodies absorb lead more easily, their brains are still developing, and they frequently put their hands and other objects into their mouths. Poverty is an additional factor for lead poisoning, as families of lower income are more likely to live in older, substandard housing.

Housing built before 1940 in Minnesota: As of 2000

The older a home is, the more likely it is to contain lead-based paint. Paints containing up to 50 percent lead were used on the inside and outside of homes through the 1950s. Older homes in the built environment are also a signal of economic decline, as populations decline and new homes are not built. The greatest percentage of pre-1940 homes are found in rural Minnesota.
Mold

Mold is a concern and a health hazard in many Minnesota homes, especially those damaged by flooding, disasters, or disrepair. Left unchecked, mold can cause respiratory problems, exacerbate asthma, and damage property. Increased heavy rainfalls and more frequent spring flooding also create more potential for mold problems in buildings throughout Minnesota.\(^{54}\)

Asbestos

Significant exposure to any type of asbestos in the home or workplace can increase the risk of lung cancer, mesothelioma, and nonmalignant lung and pleural disorders, including asbestosis, pleural plaques, pleural thickening, and pleural effusions. Asbestos can be found in older homes and buildings where it was used as insulation and building materials.\(^ {55} \)

Social Connectedness

People at all stages of life need social connection for optimal health. People with strong social connectedness and healthy relationships with family, friends, and neighborhoods, and with their culture and heritage have higher quality lives and contribute to better functioning, more vibrant communities. Healthy social environments promote individual as well as environmental health, as communities come together to protect and enhance the quality of their surroundings. Likewise, a healthy physical environment supports strong social connections.\(^ {56} \)

Growing Older

Aging also brings challenges to social connectedness, such as loss of a life-partner, and reduced ability to leave the home. Minnesotans aged 50 and over who live alone are more at risk for loneliness and are less likely to have someone to care for them if they become sick or disabled. Approximately 30 percent of Minnesotans 65 and older lived by themselves in 2010.\(^ {57} \)

Characteristics of Minnesotans over age 50: 2005

![Bar chart showing percent of Minnesotans aged 50 and over who live alone or with others, experience loneliness, or have no one to provide care if sick or disabled.

Source: Minnesota Board on Aging. (2005).\(^ {58} \)
Informal Caregivers

Minnesotans with chronic health conditions, physical disabilities, and cognitive impairment require a great deal of care. The majority of that care is provided at home by family members or other informal caregivers.

Characteristics of Minnesota’s informal caregivers: 2008

Most informal caregivers in Minnesota are female, between 45 and 64 years old, employed, and in good or excellent health, and most of them provide less than 10 hours of per week to their charges. However, an important subset of the state's informal caregivers—14 percent of them—provide between 21 and 40 hours of care per week, and 6 percent provide more than 40 hours per week of care. The caregivers that provide a larger amount of informal care are typically women, 60 or older, and caring for a child or spouse in their household with cognitive impairment or memory loss.

As an informal caregiver’s care load increases, her vulnerability to physical strain, emotional stress, and financial hardship also increases. She is more likely to report poor or fair health status, and limitations in activity due to physical, emotional, or mental problems.

Single-Parent Families

Both adults and children in households with a single parent are at greater risk for adverse health outcomes and unhealthy behaviors. These households are especially susceptible to chronic stress (often due to economic factors), social isolation, and stigma related single-parent families.

School Mobility

When families move their primary residence, children may change schools. Frequent moving during the school year can disrupt the flow of learning, weaken parent-student-teacher bonds, and make it more difficult for the child to form attachments at school. The residential mobility reflected in school moves also has implications for social connectedness within the neighborhood, for both children and parents.

Minnesota ninth-graders and changing schools: 2010

Changing schools mid-year is more common among students of color in Minnesota.

Among ninth-graders, Asian, Hispanic, American Indian and African-American students were three to four times more likely than white students to have changed schools at least once during the school year.

Incarceration

For many obvious reasons (and some less obvious), incarceration poses a number of individual and community health concerns. Incarcerated individuals are exposed to violence and infectious
diseases in close quarters, including tuberculosis. For those outside, incarceration weakens family ties, and increases community instability as members enter and are discharged—often repeatedly—from prison. This is especially true when a community has a disproportionally high number of individuals who are incarcerated.\textsuperscript{64} Incarceration also changes individual and population patterns of employment, income, and marital status, all of which ultimately have an impact on health status.\textsuperscript{65}

**Incarceration disparities in Minnesota and comparison states: 2007**

![Chart showing incarceration disparities in Minnesota and comparison states: 2007](Chart)

Source: The Sentencing Project. (2007). \textsuperscript{66}

The rate of incarceration in Minnesota is relatively low compared with other states, for example Louisiana or Wisconsin. However, Minnesota (along with Wisconsin) has one of the highest relative disparities of incarceration rates among its African-American and white populations; Minnesota currently ranks 14\textsuperscript{th} among U.S. states in this disparity, with a ratio of 9.1 African-American residents incarcerated for every single white resident. That is, for every white Minnesotan in prison, roughly nine African-American Minnesotans are also incarcerated.\textsuperscript{67}

**Community and Personal Safety**

The same factors that influence where people live and the opportunity they have to be healthy—income, employment, education—also are linked to the experience of violence. Violence is not randomly distributed; some groups of Minnesotans are more likely to be affected by violence than others.

Violence and crime affect health in multiple ways. High-crime neighborhoods keep people isolated from one another by keeping them indoors, limiting opportunities both for interaction with neighbors and for physical activity.\textsuperscript{68} Individuals who experience crime, as well as those who witness or hear about it, experience a range of effects from a delay in cognitive development (for children) to poor mental health.

Violence in schools can affect the learning environment and contribute to absenteeism. In Minnesota, between 4 and 10 percent of students missed one or more days of school because they felt unsafe at school, or on their way to or from school.
Students of color and American Indian students were more likely to report feeling unsafe than white students. In addition, witnessing or participating in violence makes youth less likely to engage in healthy behaviors like walking to school or participating in school athletics.

**Minnesota ninth-graders missing school, due to feeling unsafe: 2010**

![Bar chart showing percentages of ninth-graders missing school due to feeling unsafe by race/ethnicity.](chart1)

Domestic violence also occurs proportionately depending on income and education, for perpetrators, victims, and bystanders. Victims of domestic violence in Minnesota were less likely to have a college or graduate degree and more likely to have an associate or technical degree. Victims of domestic violence were also more likely to earn less than $30,000 annually and to rent a home or apartment, rather than own a home.70

**Minnesota domestic violence victims: 2010**

![Bar chart showing percentages of domestic violence victims by annual income.](chart2)

Source: Greater Twin Cities United Way & Minnesota Department of Public Safety, Office of Justice Programs. (2011).71
Access to Health Care

A number of the factors that shape the opportunity for health in Minnesota—education, employment, and transportation, for instance—also affect access to health care. In addition the health care workforce and the ability to acquire health care insurance also have an effect on the ability to receive health care.

Electronic Prescribing

Health care quality is affected by the ability of health systems to continually improve, to meet the needs of consumers and reduce medical errors. Electronic prescribing (or e-prescribing) is a new tool that allows providers, pharmacists and pharmacies, and insurers to securely and accurately exchange information. This lessens the likelihood of medication errors like assigning the wrong drug, dose, patient, time, rate, preparation, or route of administration, which all have serious consequences for patients and consumers.
E-prescribing in Minnesota’s health care system has grown dramatically. In 2011, the number of e-prescription transactions saw a 40 percent jump. The number of Minnesota pharmacies using e-prescriptions has increased 58 percent since 2008, and most chain and non-chain pharmacies were e-prescribing by the end of 2011.

**Health Care Workforce**

The health care workforce in Minnesota that carries out most routine and preventive care primarily consists of nurse practitioners, primary care physicians, and dentists. Regionally, some Minnesotans have greater or lesser access to primary care—for example, southeast Minnesota (where the Mayo Health System largely resides) employs a relatively high proportion of providers for its population when compared with the rest of the state, while northwest Minnesota has access to a relatively smaller pool of providers.

Over one-third of Minnesota’s counties have fewer than eight physicians per 10,000 residents, especially in the most rural areas of the state. Over 25 counties in Minnesota have fewer than four dentists per 10,000 residents.

These regional differences in primary care provider saturation may reflect Minnesota’s growing urbanization, or that many providers are choosing to practice in regions with a greater patient supply. However, health care workforce shortages can increase the distance traveled by Minnesotans seeking primary care, and ultimately reduce access for a number of rural residents.

---

* Excludes pharmacies with the pharmacy class of medical device manufacturer
** Includes pharmacies with the pharmacy class of independent, franchise, and government/federal

§ It should be noted that Mayo providers deliver a large proportion of the system’s care to non-Minnesotans.

Insurance Coverage

People who are uninsured or underinsured (that is, their insurance does not cover all necessary procedures) receive less medical care than their insured counterparts. When they do receive care, it has often been significantly delayed (often due to concerns about cost), and their condition and final outcome is frequently worse than if they had received care right away. In this way, the lack of health insurance creates a financial risk and a burden when care is received. Hospital-based charity care helps uninsured and underinsured Minnesotans, but does not compensate for gaps in health insurance coverage.

Health care coverage is provided through a system of multiple health insurers. More than half of Minnesotans get their health insurance coverage from an employer. About one-third are covered by public programs, including Medical Assistance (the state’s Medicaid program), MinnesotaCare, and Medicare. Between 2009 and 2011, the group (employer) insurance coverage rate stayed stable, but it also has not recovered from the decline observed between 2007 and 2009, when the percent of Minnesotans with employer-based coverage fell from over 62 percent to just over 57 percent, with jumps in both public coverage and the rates of uninsured Minnesotans. 

Health insurance sources in Minnesota: 2001-2011

Indicates statistically significant difference from the previous year shown. Source: Minnesota Department of Health, Health Economics Program. (2012).

Significant differences in the rate of insurance persist both by income and by race/ethnicity:

- In 2009, 17 percent of families with incomes under 200 percent of the Federal Poverty Guidelines were uninsured, compared to 3 percent of families with incomes at or over 400 percent of the Federal Poverty Guidelines
- In 2009, 25 percent of the Hispanic/Latino population, 21 percent of American Indians, and nearly 18 percent of African-American Minnesotans were uninsured, compared to 11 percent of Asians and less than 8 percent of the white population.
Uninsured Minnesotans, by income level: 2009

Lower-income families in Minnesota are less likely to have health insurance coverage.

Public Health Infrastructure

Minnesota community health boards and tribal nations: 2012
Public health departments across Minnesota work together with and within their communities to protect and improve health. Local public health departments and community health boards provide essential public health services for communities of all sizes, including monitoring population health, informing and educating people about health issues, mobilizing community partnerships to address local health problems, developing policies and plans, enforcing regulations, and assuring that people get health care.

Within the last decade, state, local, and tribal health departments have started the process of establishing consistent standards for public health, in order to ensure their capability to effectively carry out their mission. In 2011, the Public Health Accreditation Board released national voluntary public health accreditation standards for state, local, and tribal health departments. Those departments can begin applying for accreditation in 2012, and a survey of Minnesota's local and tribal health departments reveals that over three-fourths are taking steps to prepare for accreditation. The state's health department, the Minnesota Department of Health, is also preparing to apply for national voluntary public health accreditation.

**Public Health Funding**

Funding for public health care can assure access to disease prevention, health screening, surveillance, health promotion, and other population-based services. For this reason, it is an important consideration for a community’s opportunity for health. Among U.S. states, Minnesota ranks 46th in combined state and federal funding per capita for public health services, at $44.93 per resident.

**Emergency Preparedness**

Minnesota households can prepare for emergencies like floods, widespread disease outbreaks, or terrorist incidents.

All-hazard mitigation plans are an important part of a county’s arsenal in preparing for emergencies. In 2008, 36 percent of Minnesota counties had adopted all-hazard mitigation plans; by February 2011, 92 percent of counties had adopted or approved plans.
Minnesota individuals, families, and communities live healthy lives by protecting and promoting their own health, as well as each other’s health. Making healthy choices at the individual and community level requires knowledge and understanding, as well as the freedom to act on those decisions. As a result, healthy living is highly dependent on the contextual factors described in “The Opportunity for Health.”

The issues described in this section include not only what are typically considered healthy behaviors for an individual (such as engaging in physical activity, having healthy eating habits, and appropriate use of alcohol, tobacco and prescription drugs), but also ways in which people protect and promote health for others: assuring a healthy start for children; preventing and managing chronic conditions; preventing disease and injury; and promoting mental health.

### A Healthy Start for Children

#### Prenatal Care and Healthy Pregnancies

Women who access prenatal care receive some of the most important components of care to assure a healthy pregnancy, and prevent prematurity or low birth weight, both of which are significant contributors to infant mortality and high costs of care. Prenatal care encompasses a multitude of measures, including discussing a mother’s healthy choices and body changes; prenatal testing and counseling; treating medical complications like gestational hypertension, diabetes, and anemia; promoting optimal weight gain; testing for sexually transmitted infections; oral health assessment and treatment; and maternal mental health and substance abuse screening.

![Prenatal care in Minnesota: 2006-2010](image)

**White mothers have the highest rate of first-trimester prenatal care in Minnesota.**

*Source: Minnesota Department of Health, Center for Health Statistics. (2011).*

Lower rates of prenatal care in some Minnesota populations can be correlated with disparities in infant mortality rates among those same populations. The death of an infant has a profound impact on families and communities, and is an important indicator of population health.
Minnesota consistently ranks among the states with the lowest infant mortality rates. In fact, infant mortality rates have declined for all racial and ethnic populations in Minnesota over the last 20 years. Nonetheless, significant disparities persist in the mortality rates of African-American and American Indian infants, compared to all other population groups.

The causes of infant mortality vary by population: sleep-related causes, such as SIDS (sudden infant death syndrome), are a primary source of infant deaths in the American Indian community, while prematurity is the leading cause of death among African-Americans. Birth defects are the main source of infant deaths in the Asian, Hispanic, and white populations. Chronic stress, poverty, substance abuse, a lack of prenatal care, and lack of access to health care all contribute to infant mortality.

* Can be any race

Smoking and Alcohol Use during Pregnancy

Smoking during pregnancy is the single most preventable cause of maternal and infant illness and death. Smoking during pregnancy increases the risk of stillbirth, low birth weight, sudden infant death syndrome (SIDS), preterm birth, cognitive and behavioral problems, and respiratory problems in both mother and child. Children exposed to tobacco in utero are more than twice as likely to become regular smokers themselves later in life, compared with children not exposed to tobacco in utero. However, women who quit smoking before pregnancy or early in pregnancy significantly reduce their risk for these results, and also avoid delays in conception (and infertility), premature membrane rupture, placental abruption, and placenta previa.

The rate of women in Minnesota who smoke during pregnancy has remained relatively stable between 15 and 17 percent. Rates of smoking during pregnancy are significantly higher in some populations, however, such as among American Indian women, younger women (under 25), women with a high school education or less, and women who are poor or unmarried.

There is no known safe amount of alcohol to drink while pregnant, and no known safe time to drink alcohol during pregnancy. Drinking alcohol during pregnancy can cause miscarriage, stillbirth, and a range of lifelong disorders, known as fetal alcohol spectrum disorders (FASDs).
Children with FASDs can have a host of problems, including poor coordination, hyperactive behavior, difficulty paying attention, poor memory, difficulty in school, learning disabilities, speech and language delays, poor reasoning and judgment skills, vision or hearing problems, and problems with the heart, kidney, or bones.

**Smoking during pregnancy in Minnesota: 2004-2009**

Breast-feeding

Breast-feeding conveys important protective factors for infants, such as boosting immune system response and preventing obesity. Breastfeeding also promotes maternal-child bonding. The American Academy of Pediatrics recommends breast-feeding for a year or more after birth. Minnesota mothers breast-feed at a higher rate than those in the United States overall.88

Breast-feeding in Minnesota and the U.S., for children born in 2008

![Breast-feeding chart]

Childhood and Youth Experience

It is impossible to overestimate the importance of childhood** health on the rest of an individual’s life. The importance of childhood experience for health cannot be overestimated. Positive experiences in childhood (such as breastfeeding, for example) have important implications for

** For the purpose of this assessment, “child” refers to individuals between 0 and 18 years old.
lifelong health, as do negative experiences. The number of adverse childhood experiences an individual has increases his or her risk for alcoholism, depression, heart disease, liver disease, intimate partner violence, sexually transmitted infection, smoking, and suicide. These adverse events include emotional, physical, and sexual abuse and neglect, and various types of household dysfunctions (such as violence against mothers, substance abuse, mental illness, parental separation or divorce, or an incarcerated household member).90

**Violence Against Children and Teens**

**Child Abuse**

In 2009, nearly 5,000 Minnesota children were abused or neglected; 44 children suffered life-threatening injuries, and 21 died from maltreatment. The median age of abuse victims was six years old. Three-fourths of all alleged abusers are the victims’ birth parents. Some children were victims of more than one offender, and some suffered more than one form of abuse and neglect.

Children who have been physically or sexually abused are much more likely to engage in destructive behavior, such as substance use, fighting, and early sexual activity in adolescence. Research also links abuse during childhood to health risks that may emerge later, such as obesity, chronic pain and heart disease.91

**Minnesota ninth-graders and physical abuse* in the home: 2010**

![Bar chart showing the percentage of ninth-graders who have ever been hit hard or often by an adult at home by race/ethnicity.]

African-American: 18%  American Indian: 18%  Asian: 14%  Hispanic: 16%  White: 9%

In the Minnesota Student Survey, students from each of the communities of color and American Indians were more likely than white students to report that they had been hit hard or often by an adult in the household.
Sexual and Relationship Violence

Ten percent of ninth-graders and 15 percent of 12th-graders in Minnesota report experiencing some form of date violence. The highest rates were reported by American Indian and Hispanic students. Nearly one-fourth of American Indian 12th-graders reported physical or sexual violence by someone they were dating.

Minnesota students and intimate partner violence: 2010

*Minnesota ninth- and twelfth-graders who have ever been hit, hurt or threatened, or forced to do something sexual by someone they were dating*

![Graph showing percentage of students reporting intimate partner violence by grade and ethnicity.]

Teen Parenting

Minnesota teens give birth at lower rates than those in other states, and Minnesota’s teen birth rate has continued to decline in the last two decades. However, there are still striking differences in teen birth rates by racial and ethnic population: Asian, African-American, Hispanic and American Indian teen birth rates range from three to six times higher than that of white teens. 95

Minnesota’s teen birth rate for girls 15-19 years old: 2006-2010

![Graph showing teen birth rate per 1,000 births by race and ethnicity.]

Nearly one-fourth of the state’s American Indian 12th-graders report having experienced violence at the hands of someone they were dating.

The teen birth rate in Minnesota remains highest among American Indian and Hispanic teens.
Teen parents and their children face a number of unique challenges. Teen mothers are less likely to graduate from high school, and are more likely to remain unmarried, live in poverty, have large families, and receive government assistance than women who become parents after adolescence. Teen mothers are also less likely to receive timely and consistent prenatal care.97

Children of teen parents are more likely to be born at a low weight, perform poorly on cognitive and behavioral tests, be reported as abused or neglected, and be placed in foster care. They tend to perform more poorly in school than children of older parents. Daughters of teen parents have an increased risk of becoming teen parents themselves, and sons of teen parents are more likely to become incarcerated.98

**Gender Identity and Sexual Orientation**

Adolescence is a time of developing sexual awareness and gender expression, although many children are aware of their developing gender identity from a very early age. All adolescents face issues related to acceptance, self-esteem, and a growing need for intimacy and social connection. Lesbian, gay, bisexual, or transgender (LGBT) youth, however, often face discrimination, social stigma, violence, victimization, and a lack of understanding relating to their unique needs, and this can create significant barriers to health.

Estimating the statewide health needs and outcomes for LGBT youth and adults in Minnesota can be difficult, because state and national population-based surveys, including the Minnesota Student Survey, do not ask people to categorize their sexual orientation or gender identity. Local surveys and studies, however, such as the 2010 Hennepin County Survey of the Health of All the Population and the Environment (SHAPE)99 and the Boynton Health Service survey of University of Minnesota Students100 have identified important disparities in health needs, health care, and health outcomes for LGBT youth and adults.

**The Environment and Children**

Pound for pound, children breathe more air, drink more fluids, and eat more food than adults. Because children are continually growing and developing, they may be more vulnerable to environmental hazards than adults. This leads to concern about the effect of contaminants specifically on children, including allowable levels of water contaminants, mercury levels in fish intended for consumption, exposure to hazardous waste sites, air quality, lead exposure, and exposure to toxic chemicals found in meth labs.101

**Youth-Community Involvement**

Civic engagement and community involvement are important for individual, family, and community health. Research on adolescent brain development supports the need for youth to learn how to become part of a broader community, and to explore their unique contributions within that community. Positive experiences in the community provide youth with social learning experiences and help them develop a healthy social identity.

Religious participation is an indicator of community experience for Minnesota adolescents. White students in Minnesota report participating in religious activities more frequently than other racial and ethnic populations, especially among ninth-graders. Participation declines across all races and ethnic groups by 12th grade.
Minnesota ninth-graders and religious activities: 2010

Minnesota ninth- and twelfth-graders who participate in religious activities at least once per week

White ninth-graders in Minnesota report regular participation in religious activities more often than other students of color.

Eating Habits and Physical Activity

Eating Habits

Food has a direct effect on a person’s health, growth, and feeling of well-being. Eating a balanced diet is essential: different nutrients play different roles, so it is important for people to eat a variety of foods, particularly fruits and vegetables. Despite this need, about three-fourths of Minnesotans do not eat the recommended amounts of fruits and vegetables.

Poor eating habits at every age, especially those that result in too many calories, too much saturated fat and sodium, and too few nutrients (e.g., sugary drinks and a lack of whole grains) increase the risk for disease and disability. The consequences of poor nutrition include obesity, diabetes, heart disease, stroke, tooth decay, and some cancers.

Minnesota adults and healthy eating: 2003-2009

Less than one-fourth of Minnesota adults and less than one-fifth of Minnesota ninth-graders eat the U.S.D.A. recommended daily amount of fruits and vegetables.

Minnesota ninth-graders and healthy eating: 2010

Regular physical activity helps improve overall health and wellness, reduces risk for obesity, and lessens the likelihood of developing many chronic diseases like cancer and heart disease.††

The national physical activity guidelines recommend that children engage in at least 60 minutes of physical activity each day, including aerobic, muscle strengthening, and bone strengthening activity. Adults need at least two hours of moderate to vigorous-level activity every week, and muscle-strengthening activities on two or more days a week.105

Physical Activity

Regular physical activity helps improve overall health and wellness, reduces risk for obesity, and lessens the likelihood of developing many chronic diseases like cancer and heart disease.††

The national physical activity guidelines recommend that children engage in at least 60 minutes of physical activity each day, including aerobic, muscle strengthening, and bone strengthening activity. Adults need at least two hours of moderate to vigorous-level activity every week, and muscle-strengthening activities on two or more days a week.105

Minnesota students and physical activity: 1998-2010

Minnesota adults and physical activity: 2003-2009

Moderate physical activity defined as 30+ minutes of moderate physical activity (or 20+ minutes of vigorous physical activity) five or more days per week

†† For more information on rates of heart disease, cancer, and other chronic diseases, please refer to Part Two.
Physical activity among Minnesota ninth graders increased slightly between 1998 and 2010. Physical activity among Minnesota adults has remained relatively steady during the past decade.

**Use of Alcohol, Tobacco, and Prescription Drugs**

Alcohol can be consumed appropriately and responsibly, as can prescription medications. Problems occur when these substances are over-consumed, used inappropriately, or combined with other substances or with risky activities (like driving while impaired or engaging in unsafe sexual activity).

Smoking cigarettes and using other tobacco products can lead to nicotine addiction and multiple health risks, including cancer. The occasional use of tobacco, however, in the context of a cultural celebration (e.g., the use of a pipe in some American Indian ceremonies) does not necessarily carry these risks.

**Alcohol Use and Binge Drinking**

Alcohol is consumed by more people than any other drug, including tobacco. Alcohol use contributes to injury, unplanned pregnancy, poor birth outcomes and childhood development, violence, infectious disease, and chronic disease.

The younger a person begins drinking regularly, the greater the chance that person will develop a clinically defined alcohol disorder like alcoholism. Youth who start drinking before age 15, compared to those who start at 21, are far more likely to be injured while under the influence of alcohol, to be in a motor vehicle crash after drinking, or to become involved in a physical fight after drinking.\(^{108}\)

**Minnesota adults and binge drinking: 2006-2010**

![Graph showing the percentage of Minnesota adults who binge drank from 2006 to 2010.](image)

Approximately one-fourth of adult males in Minnesota reported binge drinking in 2010.

Source: Centers for Disease Control and Prevention. (2011).\(^{109}\)

Binge drinking, in which a person consumes a great deal of alcohol in a short period of time, is associated with the same serious health problems as other forms of alcohol abuse. (Binge drinking can be defined as five or more drinks at one time for men, and four or more drinks at one time for women.)
Binge drinkers are 14 times more likely to report engaging in alcohol-impaired driving than non-binge drinkers. About 90 percent of the alcohol consumed by those under 21 occurs via binge drinking.\textsuperscript{110}

Binge drinking is a particular public health concern in Minnesota, and is a major reason for Minnesota’s drop in the United Health Foundation’s \textit{America’s Health Rankings}.\textsuperscript{111} Minnesota’s rate of binge drinking is higher than in most of the rest of the U.S., although it remains lower than the rates in the surrounding states of South Dakota, North Dakota, and Wisconsin. Binge drinking in Minnesota continues to be more prevalent in men than women.

\textbf{Minnesota ninth-graders and binge drinking: 1995-2010}

Minnesota’s white and American Indian ninth-graders report the highest rates of binge drinking (defined as five or more alcoholic drinks in a row for both males and females), and the state’s Asian and Hispanic students report the lowest rates of binge drinking.

\textbf{Tobacco Use and Exposure to Secondhand Smoke}

Fewer Minnesotans smoke now than in recent history, and the remaining smokers consume fewer cigarettes per day. The proportion of adult heavy smokers in Minnesota (who consume 25 or more cigarettes per day) has shrunk from about 10 percent in 2007 to just over 6 percent in 2010.\textsuperscript{113}

Secondhand smoke is a mixture of the smoke given off by the burning end of a cigarette, pipe, or cigar, and the smoke exhaled by smokers. Even brief exposure to secondhand smoke puts nonsmokers’ health at risk, because of the thousands of chemicals being released into the air.116

The proportion of both ninth-graders and adults who smoke has decreased in Minnesota during the past decade.
Since the passage of the state’s Freedom to Breathe Act in 2007, more Minnesotans are protected from tobacco smoke in their environments by smoke-free policies at work and voluntary rules at home. In addition, fewer Minnesotans report being exposed to secondhand smoke in all locations.  

**Minnesota adult nonsmokers and secondhand smoke: 2003-2010**

A smaller proportion of Minnesota adults report being exposed to secondhand smoke in 2010 than in 2003.

![Chart showing the percentage of Minnesota adults exposed to secondhand smoke at work, in a car, and at home from 2003 to 2010.](image)

*Source: ClearWay Minnesota & Minnesota Department of Health. (2010).*

Secondhand smoke exposure among nonsmoking adults has steadily decreased over time since 2003. The percentage of nonsmoking adults exposed to secondhand smoke at work has been cut in half, from 14 to 7 percent.

Secondhand smoke exposure from 2000 to 2011 also declined among youth in middle and high school, although nonsmoking youth in high school (grades 9-12) are more likely to be exposed to secondhand smoke than nonsmoking youth in middle school.

**Minnesota students and secondhand smoke: 2000-2011**

Prescription Drug Use

Public health officials in Minnesota and nationwide are growing increasingly concerned about rising rates of improper prescription drug use, and the consequent rise in deaths from accidental overdose of prescription drugs and painkillers. Two million people nationwide reported using prescription painkillers in 2010 non-medically for the first time, and data on injury death‡‡ show a marked increase in poisoning deaths attributable to the rise in prescription drug abuse.120

Preventing and Managing Chronic Conditions

Living with a Disability

Disability can encompass a wide range of factors, including those that involve vision, hearing, movement, ambulation (or the ability to walk), and cognition. This inherent diversity makes estimates of the prevalence of disability in Minnesota vary widely, as organizations count some sorts of disability but not others. According to the U.S. Census Bureau American Community Survey,§§ nearly 10 percent of the state’s population—or almost 514,000 Minnesotans—live with one or more disabilities.121

It is important to note that disability is not automatically an indicator of poor health. However, individuals with disabilities sometimes find it more challenging to become and remain healthy, due to barriers in their physical and social environments. For example, physical activity is just as important for individuals with disabilities as those without, but accessibility or safety may

‡‡ For more information on injury deaths in Minnesota, please refer to Part Two.

§§ The American Community Survey (ACS) defines disability as a restriction in participation that results from a lack of fit between the individual’s functional limitations and the characteristics of the physical and social environment. The ACS specifically identifies difficulties in four basic areas of functioning: vision, hearing, ambulation, and cognition.
become an issue. A disability can also lead to social isolation, which can have a negative impact on mental and physical health. Finally, individuals with disabilities are at a much greater risk for abuse, in the home, at school, and in short- and long-term care settings. These challenges make it evident that all Minnesotans, regardless of ability or disability, need to live in conditions that support a healthy life.

**Children with Special Health Care Needs**

Children with special health care needs are identified as those who have, or who are at increased risk, for chronic physical, developmental, behavioral, or emotional conditions and who require health and related services of a type or amount beyond that required by normative children. Approximately 14 percent of Minnesota children have special health care needs.

**Cancer Screening**

Screening for cancer has been shown to be effective in reducing the development of the disease, which is generally more treatable when it is found early before spreading. If screening reveals a problem, diagnosis and treatment, such as removing polyps or other areas of abnormal cell growth, can occur promptly.

**Cancer screening in Minnesota and the United States: 2010**

**Preventing Diabetes**

Almost 7 percent of Minnesotans have ever been told by a doctor that they have diabetes—about 355,000 residents statewide (see *The Health of Minnesota, Part Two*). Another 85,000 are pre-diabetic or borderline diabetic.

A variety of activities can help prevent the development of diabetes, and delay the onset of diabetes for those who are pre-diabetic. Oral medications for those with pre-diabetes can also help, but medications are neither as effective nor as safe as being active, making healthy eating choices, and achieving moderate weight loss. Among Minnesotans with pre-diabetes, over three-fourths are overweight or obese.
Risk factors and care practices among Minnesotans with pre-diabetes: 2007

Among Minnesotans with pre-diabetes, over three-fourths are overweight or obese.

Oral Health

It may seem surprising, but good oral health is essential to overall health, and encompasses more than just dental check-ups. A lack of oral health can lead to cavities (or caries) and gum disease, which can in turn contribute to other diseases or conditions; conversely, certain chronic conditions can also contribute to a decline in oral health. For example, gum disease is associated with endocarditis (an infection of the inner lining of the heart), cardiovascular disease, premature birth, and low birth weight. Osteoporosis can lead to tooth loss, and individuals with diabetes and immune system disorders are more susceptible to gum and bone infections. Poor oral health can also affect self-esteem, reduce employment opportunities, and increase absenteeism.

Achieving and maintaining oral health can pose a significant challenge for some Minnesota populations, particularly those with lower incomes.

Dental visits and Minnesota adults: 2010

Source: Centers for Disease Control and Prevention. (2010).
Among children worldwide, dental caries is the most common childhood disease. Oral disease is almost completely preventable through optimal fluoride use, application of dental sealants to children’s teeth, effective oral hygiene, and regular visits to the dentist.\textsuperscript{128}

### Minnesota third-graders with caries and sealants: 2010

![Graph showing percentage of third-graders with caries experience, caries and sealants, and untreated caries by race and ethnicity for 2010.]

\textit{Source: Minnesota Department of Health, Oral Disease Prevention Unit. (2011).}\textsuperscript{129}

### Preventing Disease and Injury

#### Immunizations

Immunizing individuals, especially children, helps protect the health of the entire community. Immunization is especially important in protecting those who cannot be immunized, such as children too young to be vaccinated, children and adults who cannot be vaccinated for medical reasons, and those who cannot make an adequate response to vaccination. It also protects those who have received a vaccine, but who have not developed immunity to the disease.

### Older adults and immunization in Minnesota: 2001-2010

![Graph showing percentage of adults 65+ who received flu and pneumonia vaccinations in the past year.]

Nearly the same proportions of adults 65 and older have been immunized against flu and pneumonia in the past year.

\textit{Source: Centers for Disease Control and Prevention. (2011).}\textsuperscript{130}

---

56  The Health of Minnesota  

Healthy Living in Minnesota
Immunization also slows and halts disease outbreaks, and lessens the exposure of children and adults to disease germs passed by the unvaccinated. In about half of Minnesota counties, less than 60 percent of children are up-to-date on immunizations; in the majority of Minnesota counties, less than 90 percent of children are up-to-date.** Statewide, about 58 percent of children have received the entire recommended series of vaccines.  

Preventing Sexually Transmitted Infections

Delay of Sexual Activity

One effective way to prevent the transmission of sexually transmitted infections (or STIs, which are also known as sexually transmitted diseases) among youth is to delay the onset of sexual

---

** Childhood immunization rates are measured annually through the Minnesota Immunization Information Connection (MIIC) immunization registry. At least 80 percent of providers participate in MIIC in most counties.

*** Series of recommended vaccines for children between 24 and 35 months old: 4+ DTaP (Diphtheria, tetanus and acellular pertussis), 3+ polio, 1+ MMR (Measles, mumps and rubella), Completed Hib (Haemophilus influenza type b), 3+ Hep B (Hepatitis B), 1+ varicella (chickenpox), Completed Prevnar (Pneumococcal conjugate vaccine by brand name).
activity. Minnesota’s ninth-graders report lower rates of sexual activity than in the mid-1990s, although this rate has leveled off in recent years.

### Vaccination

Each year in the U.S., about 12,000 women get cervical cancer. Almost all of these cancers are associated with the genital human papillomavirus (also called HPV) virus, the most common sexually transmitted infection. Approximately 20 million Americans are currently infected with HPV. Another 6 million people become newly infected each year. HPV is so common that at least 50 percent of sexually active men and women get it at some point in their lives.

### Minnesota teen girls (ages 13-17) and HPV vaccination: 2008-2010

*Source: Centers for Disease Control and Prevention. (2010).*
Two vaccines are available to protect females against the types of HPV that cause most cervical cancers and most genital warts. Vaccination is recommended for 11 and 12 year-old girls, and for females 13 through 26 years of age, who did not get any or all of the HPV shots when they were younger. One vaccine is available for boys and men, 9 through 26 years of age, to protect against most genital warts and anal cancers.\textsuperscript{134}

In 2010, almost 38 percent of adolescent girls in Minnesota had completed the three-dose series of HPV vaccines, up from 27 percent the year before. The national HPV vaccination rate in 2010 was 32 percent.

**Condom Use**

Consistent condom use is also an effective way to prevent STIs, and failure to use condoms consistently makes sexually active youth much more vulnerable to STIs. Among sexually active ninth-graders, African-American students are the most likely to report that they “always” use a condom, while Asian students are the least likely to report consistent condom use. Fewer than half of 12th-grade students in all racial/ethnic groups report consistent condom use, although it is possible that those reporting inconsistent use are using other methods of birth control besides or in addition to condoms.

*Source: Minnesota Student Survey. (2011).\textsuperscript{135}*

**Hand washing**

Hand washing is one of the easiest and most important actions that anyone can take to prevent disease transmission, yet many people do not consistently wash their hands when appropriate. Three observational studies of hand washing practices in Minnesota found consistent gaps in hand washing between females and males:

- (2003) Back to ‘50s Car Show Event: 64 percent of females washed their hands; 30 percent of males
- 2003 State Fair: 65 percent of females washed; 39 percent of males
- 2004 State Fair: 75 percent of females washed; 51 percent of males\textsuperscript{136}
Safety Belts and Booster Seats

Safety belts and booster seats are highly effective in reducing injury and death from motor vehicle crashes. Minnesota reached a statewide seatbelt use rate of 93 percent in 2011, the highest in the state’s history. Rates of use had been steadily increasing since 2003, and increased even more with passage of the state’s Primary Seat Belt Law in 2009. The lowest rates of safety belt use can be found among young people, particularly males driving pickup trucks.

Booster seats are also required by law in Minnesota, for children who have outgrown a forward-facing harnessed restraint but who are still too small to correctly fit into an adult safety belt (usually around age four, and for those who weigh between 40 and 60 pounds). In a 2011 survey,

- Two-thirds of children were found to be properly restrained in a booster seat
- Female caregivers were more likely than males to put children in boosters
- Only half of young caregivers (ages 16-29) used booster seats
- If the driver was not wearing a seatbelt, then only 27 percent of the children were in a booster seat

Safety belt use in Minnesota: 2003-2011

![Minnesotans’ use of safety belts has steadily increased since 2003.](image)

Promoting Mental Health

When a person experiences mental or emotional health issues, it can affect his or her everyday functioning. Mental and emotional health struggles can place significant strains on relationships, affect the ability to work, and lead to self-harm. Depression and anxiety can affect a person’s ability to participate in health-promoting activities, such as physical activity, and can also disrupt connections to helpful social supports.

Physical or medical conditions can also lead to mental health struggles. Physical pain and depression are strongly associated: More than 65 percent of adults with a mental disorder reported also having at least one general medical disorder. The connections between mental and physical health are complex and move in both directions. Socioeconomic factors, such as low income and poor educational attainment, are associated with both mental disorders and medical conditions.
When adolescents experience emotional distress, it can affect their ability to develop, to learn, and to make sound decisions about their behavior. This distress can also lead to immediate physical dangers in adolescents, like cutting and other forms of self-harm, as well as suicide and attempts at suicide. Minnesota’s American Indian and Hispanic students report experiencing higher levels of stress than their peers, and female students report higher rates of emotional stress than males across all races and ethnic groups.

**Minnesota ninth-graders and emotional distress: 2010**

*Minnesota ninth-graders who have felt nervous, worried, or upset "all" or "most of the time" during the last 30 days*

![Bar graph showing the percentage of ninth-graders who have felt nervous, worried, or upset.](source)

Protective factors like the involvement of caring friends and adults moderate the effects of negative life experiences, and improve the opportunity for positive health outcomes and overall well-being in adolescents. Even one caring adult can make a significant difference in the emotional health of an adolescent.

In Minnesota, three-fourths of ninth-graders in each racial and ethnic group reported feeling that adult relatives besides their parents cared about them “very much” or “quite a bit.” More than two-thirds of ninth-graders of color felt that their friends cared about them “very much” or “quite a bit,” although white students were the most likely to report feeling that their friends cared about them.

Conclusion: Meeting Challenges with Strengths

This statewide health assessment identifies many concerns for health, challenges, and significant and alarming disparities in health status among Minnesota’s populations. These issues reveal that Minnesota has ample opportunity to improve health; partners intend to focus on this opportunity in Healthy Minnesota 2020, the statewide health plan to be developed later in 2012.

However, an assessment of the state would not be complete without a description of the state’s strengths and assets. In the context of a statewide health assessment, the concept of “strengths and assets” refers to the many types of human, social, economic, and organizational resources than stakeholders can leverage to improve the health of all, and ensure a healthy future for the state. Minnesotans can make progress not by focusing on problems, but by generating energy and harnessing resources for change.\(^\text{145}\)

The Healthy Minnesota Partnership, along with feedback from public commenters, offered numerous suggestions for presenting Minnesota’s strengths and assets. Please note: the references offered are provided as examples, but are not a complete listing of all of the state's relevant resources.

**The People of Minnesota**

- The children of Minnesota remain the future of the state\(^\text{146}\)
- Growing racial, ethnic and cultural diversity brings significant economic contributions and a richness of perspectives, skills, experience, and innovative ideas to the state\(^\text{147}\)
- Older Minnesotans provide an invaluable source of wisdom and experience; as retirees they often commit large amounts of time to community involvement and volunteerism\(^\text{148}\)
- Minnesota’s youth never cease to amaze with their passion for the world and their commitment to make a difference\(^\text{149}\)
- Minnesota is a source of innovative and effective leaders at the local, state and national levels

**Communities in Minnesota**

- Minnesota has a history of caring and extensive community involvement by individuals, families, and organizations. For example, Minnesota ranks third in the nation for its rate of volunteering; the Twin Cities ranks first among large cities\(^\text{150}\)
- Minnesota has a commitment to and many years of experience with effective partnerships across a wide variety of public and private sectors, including a unique partnership between state and local public health departments that has grown strong through over 35 years of experience working on public health issues together\(^\text{151}\)
- Minnesota is known for a strong non-profit sector, philanthropic foundations, and numerous community-based organizations\(^\text{152}\)
- Employers based in Minnesota historically contribute to and participate in the community\(^\text{153}\)
- Multiple sectors of Minnesota collaborate with energy and ongoing commitment on a wide variety of efforts\(^\text{154}\)
- Minnesota has a high rate of participation in numerous and diverse faith communities with active commitment to helping others\(^\text{155}\)
- Minnesotans participate in government and civic life at a high rate\(^\text{156}\)
Being community-minded in Minnesota: 2009

Minnesota’s Systems

- Minnesota has historically committed to and made a significant investment in education.
- Minnesota’s vibrant agriculture sector is expanding the availability of farmers’ markets, to create economic opportunity and make fresh food more available in local communities.
- Minnesota has an international reputation of having a high-quality health care system and medical research, and state-of-the-art medical centers.
- Minnesota is known internationally for its strong business community.
- Visitors and residents can find a variety of tourist destinations throughout the state, as well as an extensive system of parks and trails.
- Minnesotans are protected from the unexpected with highly effective disease surveillance, health protection, and emergency response systems.

The “Minnesota Approach”

- Minnesota has a national reputation for and a history of innovative and forward-thinking initiatives. State partnerships work to eliminate health disparities, focus on policy, systems, and environmental change, and engage the business community in creating greater opportunity by working to remove socioeconomic inequality.
- Minnesota’s researchers and practitioners regularly collaborate to develop innovative and effective solutions to challenging problems.
- A number of Minnesota institutions use multi-sector, multi-discipline, and cross-cutting collaborative approaches to create lasting change.
- Minnesota encourages a growing environmental awareness and commitment to land stewardship.
- Minnesotans ingenuously and proactively work toward building sustainable communities.

Conclusion
Appendix: Healthy Minnesota Partnership

**Charge**

The Healthy Minnesota Partnership was created to develop innovative public health priorities, goals, objectives, and strategies to improve the health of all Minnesotans, and to ensure ownership of these objectives and priorities in communities across the state of Minnesota. The Healthy Minnesota Partnership resides online: [http://www.health.state.mn.us/healthymnpartnership/](http://www.health.state.mn.us/healthymnpartnership/)

**Membership**

The efforts of the Healthy Minnesota Partnership are intended to benefit the state as a whole, and the membership of the partnership reflects a broad spectrum of interests.

As of April 2012, the following organizations were represented in the Healthy Minnesota Partnership:

Jeanne Ayers  
Minnesota Department of Health  
Alfred Babington-Johnson  
StairStep Foundation  
Ken Bence  
Minnesota Public Health Association  
Kari Benson  
Minnesota Board on Aging  
Janny Dwyer Brust  
Minnesota Council of Health Plans  
Karen Cadigan  
Minnesota Department of Education  
Rachel Callanan  
American Heart Association  
Michael Connelly  
Xcel Energy  
Rhonda Degelau  
Minnesota Association of Community Health Centers  
Liz Doyle  
TakeAction Minnesota  
Ed Ehlinger  
Minnesota Department of Health  
John R. Finnegan, Jr.
