SUPPLEMENTAL TECHNICAL INFORMATION

Overview

Chronic Conditions in Minnesota: New Estimates of Prevalence, Cost and Geographic Variation for Insured Minnesotans, 2012

In January 2016, the Health Economics Program of the Minnesota Department of Health (MDH) released a report on chronic conditions prevalence and spending for Minnesotans with health insurance coverage using 2012 calendar year data from the Minnesota All Payer Claims Database (MN APCD).¹ The report presented findings on the number and rate of insured Minnesota residents who had a chronic condition, along with the average and total annual amount of health care spending for Minnesota residents with and without a chronic condition. The data were presented at both the overall state and county levels. The report also presented findings on the number and rate of insured Minnesota residents who had one or more of ten select and common chronic

conditions, along with the average and total annual amounts of health care spending for residents with those conditions.

This document provides detailed supplemental tables to discriminating readers, including point estimates for observed and expected prevalence, given certain population demographics, and spending for select chronic conditions at the county level. The supplemental data allow for statistical comparisons of county level estimates to the state average.

Also included are rates per thousand residents at the county level for those with any chronic condition and for ten select conditions, each broken down into three age categories: 1) under 18 years of age; 2) between 18 and 64 years of age; and 3) 65 years of age and older. Rates based on fewer than 11 residents are masked to ensure privacy. The rates reported are raw rates, meaning they have not been adjusted for differences in demographic factors across the geographies.

¹ The report is available online: <http://www.health.state.mn.us/healthreform/allpayer/publications.html>

Methods

MDH conducted this study using data from the MN APCD, a large repository of health insurance claims, enrollment information, and costs for health care services and pharmacy benefits provided to Minnesota residents.² Both private and public insurers of Minnesota residents submit information on health care and pharmacy transactions to the MN APCD.

Some health care transactions are not included in the MN APCD. These include:

- Care provided to non-Minnesota residents, or paid for by the Indian Health Service, U.S. Department of Veterans Affairs, Workers' Compensation, Tricare, or the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS);³
- Care provided to the uninsured – such claims are typically not presented to payers of health care costs who are data submitters to the MN APCD;
- Medicare services for the fee-for-services population with substance abuse conditions - the federal government currently withholds such claims from submission;
- Care paid for by health plans that have a small footprint in the state, with annual medical claims less than \$3 million or pharmacy claims less than \$300,000.

The estimates presented in this supplement document and its accompanying report are likely conservative because in order to be identified with a chronic disease, a patient must have sought care, had at least two diagnoses for the same disease recorded, and had the claim considered valid by an insurance company. In other words, patients who do not present for care, or do not have an insurer pay for a portion of the care, are not included in these estimates.

The analysis was limited to Minnesota residents with at least three months of

² Additional information about the MN APCD is available online: www.health.state.mn.us/healthreform/allpayer/

³ Individuals with multiple sources of insurance coverage, for example, employer-based coverage in addition to coverage for certain services through the U.S. Department of Veterans Affairs, are most likely represented in the data.

⁴ The analysis used version 10.0 of the Johns Hopkins ACG® System with stringent selection criteria that err on the side of under-identifying chronic diseases. We used version 11 of the ACG System to more accurately identify patients with rheumatoid arthritis.

documented enrollment in both medical and pharmacy insurance in 2012. County level estimates were based on the ZIP Code of each patient's residence. Two approaches were used to identify the presence of chronic disease, both relying on software developed at the Johns Hopkins Bloomberg School of Public Health:⁴

- To identify the presence of any chronic condition, patients needed to have two or more diagnoses for at least one of the conditions listed in Appendix A of the report.
- To identify the ten select chronic conditions that we examined more closely, patients generally needed to have two or more diagnoses, or use medication that treats the condition.⁵

The comparison of county level prevalence and spending to statewide averages was prepared with indirect standardization to adjust for differences in age, sex, length of enrollment, payer mix (private, Medicaid, Medicare), as well as the degree to which residents were eligible for both Medicaid and Medicare (dual eligible).⁶

Definitions

Observed prevalence, or raw prevalence, is simply the number of people within each county who were diagnosed with a specific chronic condition. People with conditions residing in ZIP Codes that crossed county lines were assigned by proportion to each county, relative to the proportion of the total U.S. Census 2010 ZIP Code population located within that county. MDH derived these proportions using TIGER/Line Shapefiles data⁷ in ESRI ArcGIS.⁸

Expected prevalence is the number of people in the population who have the chronic condition, adjusting for factors that are directly related to prevalence.

⁵ The second approach raises estimates of prevalence by about three percentage points.

⁶ For the remainder of this technical supplement, data on Medicaid enrollees broadly include residents eligible for Minnesota public health programs, including MinnesotaCare.

⁷ Census 2010 TIGER/Line Shapefiles data. <https://www.census.gov/geo/maps-data/data/tiger-line.html>

⁸ ESRI ArcGIS 10.2.2 for Desktop. Environmental Systems Research Institute, Redlands, CA.

Expected prevalence and spending were derived using indirect standardization. For expected prevalence, steps included:

Step 1) Breaking out categories (i.e., stratifying) by:

- a. Age (under 18, 18-24, 25-34, 35-44, 45-54, 55-64, 65 and older);
- b. Sex (male or female);
- c. Payer category (Medicare, Medicaid, or private insurance);
- d. Dual eligibility (Medicare/Medicaid dual or not); and
- e. Length of enrollment (12 months versus less than 12 months).

Step 2) Calculating the rate (per 1,000 residents) at the state level for each combination of categories.

Step 3) Multiplying the state rates by the number of residents at the county level for each combination.

Step 4) Summing the results across the combinations (strata) to derive an expected county prevalence.

The same process was used for spending, except that average spending for people with each condition was calculated for each stratum at the state level, then multiplied by the number of residents at the county level for each combination, and then summed and divided by the number of residents in each county to derive expected average spending.

Many tables present counts of people with conditions, but no rates. If needed, rates can be calculated by dividing the observed counts by the number of residents for that county and then multiplying by 1,000 for a rate per 1,000 residents. Standard errors and significance levels in the tables are for county comparisons with the overall state count or spending average. We do not recommend making direct county-to-county comparisons based on these data because such a comparison would not account for the fact that rates

across counties may vary considerably by differences in age, sex, payer, and dual-eligibility composition. County-to-county comparisons would require standardizing counties to the demographic make-up of an index population.

Standard errors (StdErr) for counts were calculated using the following formula:

$$StdErr = \sqrt{\frac{observed\ count / expected\ count}{expected\ count}}$$

Standard errors for spending were calculated using the following formula:

$$StdErr = \sqrt{\frac{observed\ average\ spending / expected\ average\ spending}{N}}$$

Significance levels were based on a 95 percent confidence interval around the Standardized Morbidity Ratio (SMR), which is calculated using these formulas:

SMRs for counts were calculated using the following formula:

$$SMR = \frac{observed\ count}{expected\ count}$$

SMRs for spending were calculated using the following formula:

$$SMR = \frac{observed\ average\ spending}{expected\ average\ spending}$$

Confidence intervals (CI) were calculated using the following formula:

$$CI = SMR \pm (1.96 \times StdErr)$$

If the upper confidence limit fell below 1.0, or the lower confidence limit was above 1.0, then the prevalence (count) or average spending was significantly lower or higher than expected.
