Introduction

Healthcare-associated infections (HAIs) are infections associated with receiving medical care in a hospital or other health care facility. According to the Centers for Disease Control and Prevention (CDC), there were an estimated 687,000 HAIs in U.S. acute care hospitals in 2015 and approximately 72,000 HAI-associated deaths (CDC, 2018). The widespread use of antibiotics has resulted in an increase in antibiotic-resistant infections, leading to more than 2.8 million illnesses and more than 35,000 deaths each year in the U.S. (CDC, 2019). In hospitals and other health care settings, antibiotic stewardship programs (ASPs) employ coordinated efforts to improve the effective use of antibiotics. Work done in these programs is an important part of broader health care facility efforts to reduce antibiotic resistance.

Minnesota acute care hospitals participating in the Centers for Medicare and Medicaid Services (CMS) Hospital Inpatient Quality Reporting Program and Inpatient Prospective Payment System (PPS) use the National Healthcare Safety Network (NHSN) to report HAIs and other select measures to fulfill reporting requirements. NHSN is a secure, internet-based surveillance system managed by CDC.

The purpose of this report is to summarize statewide HAI data reported by Minnesota acute care PPS hospitals to NHSN and the progress of all Minnesota acute care hospitals towards implementing CDC’s antibiotic stewardship core elements as reported through the NHSN annual facility survey.

This report includes five HAIs reported by acute care PPS hospitals:

- Central line-associated bloodstream infections (CLABSI)
- Catheter-associated urinary tract infections (CAUTI)
- Surgical site infections (SSI) following colon surgery and abdominal hysterectomy
- Positive laboratory-identified (LabID) results for methicillin-resistant Staphylococcus aureus (MRSA) in the bloodstream
- Positive laboratory-identified (LabID) results for Clostridioides difficile infection (CDI) in stool

This report also includes information reported to NHSN by Minnesota hospitals on their implementation of certain antibiotic stewardship program (ASP) components, or ASP core elements.
HEALTHCARE-ASSOCIATED INFECTIONS IN MINNESOTA ACUTE CARE HOSPITALS

Key Findings

In 2018, Minnesota acute care hospitals reported significant advancement in institutional antibiotic stewardship, with 76% of all hospitals reporting implementation of all seven antibiotic stewardship program core elements. This is a 33% increase from 2017 (57%).

As compared with predicted rates, Minnesota PPS acute care hospitals reported improvement across most HAI types in 2018. Predicted rates are determined by CDC based on baseline data from 2015.

- Fewer central line-associated bloodstream infections (CLABSI) than predicted
- Fewer catheter-associated urinary tract infections (CAUTI) than predicted
- Fewer hospital-onset *Clostridioides difficile* infections (CDI) than predicted, as identified through laboratory-identified (LabID) testing of stool (feces)
- Fewer hospital-onset cases of methicillin-resistant *Staphylococcus aureus* (MRSA) bacteria in the bloodstream than predicted
- Similar number of surgical site infections (SSI) following colon procedures and abdominal hysterectomies as predicted

**Methods**

**NHSN Data**

Hospitals self-report data to NHSN according to the NHSN surveillance protocol developed by CDC. Although efforts are made through education and training to improve the standardization and understanding of NHSN surveillance guidelines, definitions, and criteria, there can be variability in interpretation and application, leading to differences in reporting practices among hospitals.

Minnesota Department of Health (MDH) accesses NHSN data through a data use agreement (DUA) with CDC that was initially established in 2013 and updated in November 2017. The DUA establishes a formal data access and data use relationship between MDH and CDC, and stipulates that MDH may only use the data for HAI surveillance and prevention purposes. For more information about MDH NHSN DUA, refer to National Healthcare Safety Network (NHSN) ([https://www.health.state.mn.us/facilities/patientsafety/infectioncontrol/nhsn.html](https://www.health.state.mn.us/facilities/patientsafety/infectioncontrol/nhsn.html)).

This report covers data that were collected between January and December 2018 and were downloaded from the NHSN secure internet platform on August 16, 2019; any changes made to the data after this date are not reflected in this report.

There might be variation between results published in this report and results published elsewhere. Hospitals have the ability to modify their NHSN data at any time and as such, results might appear to vary if other sources use different data collection periods or downloaded data from NHSN on a different date.

For more information about NHSN, refer to CDC: National Healthcare Safety Network (NHSN) ([https://www.cdc.gov/nhsn/](https://www.cdc.gov/nhsn/)).

**Standardized Infection Ratio (SIR)**

The standardized infection ratio (SIR) is a summary measure used to track HAIs at a national, state, or local level over time. The SIR accounts for various facility and/or patient-level factors that contribute to HAI risk. The SIR is calculated by dividing the number of observed infections by the number of predicted infections. The number of predicted infections is calculated based on 2015 national HAI aggregate data, using a multivariable regression model and adjusted using factors found to be significant predictors of HAI incidence.

\[
\text{SIR} = \frac{\text{Observed Infections}}{\text{Predicted Infections}}
\]

- An SIR greater than 1.0 indicates that more infections were observed than predicted
- An SIR less than 1.0 indicates that fewer infections were observed than predicted

Risk Adjustment

The SIRs presented in this report are adjusted for risk factors known to be significantly associated with differences in infection incidence, such as type of patient care location, bed size of the hospital, patient age, and other factors. NHSN incorporates information on many important factors that might put a patient at risk for an HAI, but not all clinical details are collected in this system. Therefore, each patient has a different set of risks that might not be fully accounted for in the calculation of the standardized infection ratio.

U.S. Department of Health and Human Services (HHS) SIR Goals

The U.S. Department of Health and Human Services (HHS) sets national HAI reduction targets through the National Action Plan to Prevent Health Care-Associated Infections: Road Map to Elimination. In October 2016, HHS announced new targets for acute care hospitals using national 2015 NHSN data as the baseline. These targets are in effect for a five-year period during 2015–2020.

The 2020 HHS SIR goals for the HAIs included in this report are as follows:

- CLABSI and MRSA: 0.50
- CAUTI: 0.75
- SSI and CDI: 0.70

Data Quality

All data presented in this report are self-reported by hospitals to NHSN. In order to ensure complete and accurate data, MDH conducts quarterly data quality reviews of NHSN data for Minnesota acute care PPS hospitals to identify internal inconsistencies and outlier values that could be erroneous. For more information about MDH NHSN data quality reviews, refer to [National Healthcare Safety Network (NHSN)](https://www.health.state.mn.us/facilities/patientsafety/infectioncontrol/nhsn.html).

Central Line-Associated Bloodstream Infections (CLABSI)

A central line is a tube placed in a large vein to allow access to the bloodstream and administration of intravenous (IV) medications. A central line-associated bloodstream infection (CLABSI) can occur when bacteria or other germs travel along a central line and enter the bloodstream. When inserted incorrectly or if the insertion site is not kept clean, a central line can become a pathway for germs to enter the body, potentially resulting in a serious bloodstream infection.

This report includes CLABSI data reported by Minnesota acute care PPS hospitals from units required for CMS reporting, including adult, pediatric, and neonatal intensive care units (ICU), and adult and pediatric medical, surgical, and medical/surgical wards. It does not include CLABSI data that might have been reported voluntarily from other units, such as specialty wards.

Catheter-Associated Urinary Tract Infection (CAUTI)

A urinary catheter is a tube placed in the bladder to drain urine. A catheter-associated urinary tract infection (CAUTI) can occur when bacteria or other germs travel along a urinary catheter, resulting in a bladder or kidney infection.

This report includes CAUTI data reported by Minnesota acute care PPS hospitals from units required for CMS reporting including adult and pediatric intensive care units (ICU), adult and pediatric medical, surgical, and medical/surgical wards, and CMS-certified inpatient rehabilitation wards. It does not include CAUTI data that might have been reported voluntarily from other units, such as specialty wards.

Surgical Site Infections (SSI)

A surgical site infection (SSI) occurs after surgery in the part of the body where the surgery took place. These infections might involve only the skin but could also be more serious if tissue under the skin or internal organs are infected. SSIs sometimes take extended time periods after surgery to develop. Symptoms might include fever, redness or pain around the surgical site, or drainage of fluid from the wound.

This report includes SSIs reported by Minnesota acute care PPS hospitals following surgical procedures required for CMS reporting including colon surgeries (COLO) and abdominal hysterectomies (HYST) from hospitals that perform those procedures. It does not include SSI data that might have been reported voluntarily for other types of surgical procedures. The risk-adjustment model used to calculate SIR is the complex admission/readmission model, which includes procedures in adult patients that stay overnight in the hospital. This model includes more complicated and severe infections involving deep tissue and organ space and excludes superficial infections that involve only the top layers of skin and tissue.

Methicillin-Resistant *Staphylococcus aureus* (MRSA) Bacteremia Laboratory-Identified Events (LabID)

Methicillin-resistant *Staphylococcus aureus* (MRSA) infections are caused by bacteria that are resistant to certain types of drugs. MRSA can cause skin or wound infections. Sometimes, MRSA can infect the blood and cause serious illness and even death.

MRSA LabID events rely on laboratory data only and do not require patients to be ill to have a positive result. Sometimes patients will have multiple lab tests during their treatment that are positive for a MRSA infection. The first positive test that identifies a MRSA infection is called the incident infection, which means that the patient did not have another positive test result for MRSA within the last 56 days.

This report only displays incident MRSA bloodstream infections identified on or after the fourth day of hospitalization (health care facility-onset) in inpatient locations reported by Minnesota acute care PPS hospitals.

**Clostridioides difficile Infection (CDI) Laboratory-Identified (LabID) Events**

*Clostridioides difficile* (CDI) is a type of bacteria that causes severe diarrhea and can be deadly. CDI usually occurs in people who have recently taken antibiotics and have been under medical care.

CDI LabID events rely on laboratory data only and do not require patients to be ill to have a positive result. Sometimes patients will have multiple lab tests during their treatment that are positive for CDI. The first positive test that identifies CDI is called the incident infection, which means that the patient did not have another positive test result for CDI within the last 56 days.

This report only displays incident CDI identified on or after the fourth day of hospitalization (health care facility-onset) in inpatient locations reported by Minnesota acute care PPS hospitals.

Antibiotic Stewardship Program Core Elements

Hospital antibiotic stewardship programs (ASPs) have been shown to improve prescribing and treatment practices and to reduce negative impacts of antibiotic use. In 2014, CDC recommended that all acute care hospitals implement an ASP. That same year, CDC published guidance titled, The Core Elements of Hospital Antibiotic Stewardship Programs (CDC, 2014). Recognizing that hospitals differ in terms of organizational structure, care provided, and available resources, the core elements are intended to provide flexible guidance to implement the most essential components of an ASP. With this guidance, CDC highlights leadership commitment and a multidisciplinary approach to antibiotic stewardship and regards an ASP that incorporates all seven core elements as a comprehensive program.

For several years, the NHSN annual hospital survey has included questions intended to assess a hospital’s adoption of the ASP core elements. In 2018, some of these questions were updated to better reflect antibiotic stewardship practice. However, some of these changes have influenced our ability to assess progress over time. The survey questions included for each core element, and the answers required to judge whether the program includes or “meets” that core element, as well as notable changes in 2018, are listed in Table 11 below.

</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td>Wording change to “policy or formal procedure”. Words change of some antibiotics require approval to specify prior authorization. Added:</td>
</tr>
<tr>
<td>One or more of:</td>
<td></td>
</tr>
<tr>
<td>• Policy to document antibiotic clinical indications.</td>
<td></td>
</tr>
<tr>
<td>• Treatment recommendations for common conditions.</td>
<td></td>
</tr>
<tr>
<td>• Formal procedure for ongoing assessment of need for antibiotics (antibiotic time out).</td>
<td></td>
</tr>
<tr>
<td>• Some antibiotics require physician or pharmacist approval.</td>
<td></td>
</tr>
<tr>
<td>• Physician or pharmacist reviews antibiotic prescriptions and communicates with prescribers.</td>
<td></td>
</tr>
<tr>
<td><strong>Tracking</strong></td>
<td>Wording change to “policy or formal procedure”. Added:</td>
</tr>
<tr>
<td>One or more of:</td>
<td></td>
</tr>
<tr>
<td>• Adherence to documentation policy is monitored.</td>
<td></td>
</tr>
<tr>
<td>• Adherence to treatment recommendations is monitored.</td>
<td></td>
</tr>
<tr>
<td>• Overall antibiotic use is monitored.</td>
<td></td>
</tr>
<tr>
<td><strong>Reporting</strong></td>
<td>Wording change to “policy or formal procedure”. Added:</td>
</tr>
<tr>
<td>One or more of:</td>
<td></td>
</tr>
<tr>
<td>• Physician or pharmacist reviews antibiotic prescriptions and communicates with providers.</td>
<td></td>
</tr>
<tr>
<td>• Prescribers receive facility reports on overall antibiotic use.</td>
<td></td>
</tr>
<tr>
<td>• ASP provides feedback to prescribers.</td>
<td></td>
</tr>
<tr>
<td><strong>Education</strong></td>
<td>Specifies staff types and frequency of education.</td>
</tr>
<tr>
<td>AS education programs for clinicians and other relevant staff.</td>
<td></td>
</tr>
</tbody>
</table>

The following section details survey results from Minnesota hospitals and, where available, national results. Results from all participating acute care hospitals are included in this section, including critical access hospitals (CAH), and specialty hospitals that voluntarily report these data to NHSN. In reviewing results comparing Minnesota and U.S. hospitals, it is important to note that the proportion of Minnesota NHSN hospitals classified as CAHs is greater than the proportion of CAHs nationwide. In 2017, CAHs accounted for 58% of 131 Minnesota hospitals reporting to NHSN compared with 22.5% of 4,992 nationwide.
Figure 8. Proportion of Hospitals Meeting All Seven Antibiotic Stewardship Program Core Elements by Year and Location

Number of Minnesota hospitals reporting (n) = 128 in 2015; 124 in 2016; 131 in 2017; 127 in 2018

Figure 12. Proportion of Minnesota Hospitals Meeting All Seven Antibiotic Stewardship Program Core Elements by Year and Hospital Bed Number
The NHSN hospital survey asks about several commonly used ASP interventions. To meet the ASP “Action” core element, respondents must indicate that one or more of the listed interventions are used in their facilities. The table below shows the proportion of Minnesota hospitals reporting implementation of each intervention.
