Hemoglobin variant trait is common and can occur in any race or ethnicity. You may have heard of sickle cell trait before, while not exactly the same, sickle cell trait and hemoglobin variant trait are similar.

What is hemoglobin variant trait?
Hemoglobin variant trait (AV) is an inherited condition which affects the hemoglobin in your red blood cells.

- Hemoglobin is a protein in red blood cells. The job of hemoglobin is to carry oxygen through the body.
- Each person inherits two hemoglobin genes – one from each parent. A normal gene will make normal hemoglobin (A). A specific change in the hemoglobin gene will make hemoglobin variant (V).
  - Red blood cells with normal hemoglobin (A) are doughnut shaped;
  - Red blood cells with hemoglobin variant (V) can have their function or shape changed.
- People with hemoglobin variant trait have both normal hemoglobin (A) and a variant hemoglobin (V) in their red blood cells. A test called a hemoglobin electrophoresis cascade can tell us more about the specific change that has occurred in a person with hemoglobin variant trait.

What is a gene?
Genes are the instructions in our DNA that tell our bodies how to function. For example, genes determine eye color, hair color, and height. We inherit half our genes from our mother and half from our father.

How do you know if you have hemoglobin variant trait (AV)?
A simple blood test called a hemoglobin electrophoresis can tell your hemoglobin type. Talk with your healthcare provider if you have more questions about hemoglobin trait or if you want to be tested.

It is important to know if you have hemoglobin variant trait.
Hemoglobin variant is inherited from your parents, like hair or eye color. If one parent has hemoglobin variant trait, there is a 50% (1 in 2) chance with each pregnancy of having a child with hemoglobin V trait.

Hemoglobin variant trait is not a disease, and usually has no symptoms. You may have hemoglobin variant trait and not know it.

If both parents have an abnormal hemoglobin trait, like hemoglobin variant trait, there is a 25% (1 in 4) chance with each pregnancy of having a child with a hemoglobin disorder. Hemoglobin disorders are life-long illnesses that can result in serious health problems.
What you should know if you have hemoglobin variant trait...

1. You will always have trait.

2. It is not a disease and can never become a disease.

3. Hemoglobin variant trait does not cause health problems.

4. Hemoglobin variant trait will not cause anemia (low blood cell count, low hemoglobin count) if this happens, talk to your health care provider.

5. It is important to know your hemoglobin trait status for future family planning for yourself and your family.
